SIR,—The real problem of prevention of rheumatism is, as has been clearly shown in the recent reports of commissions, one rather of social hygiene than of strictly medical practice. That, however, does not justify any slackening in our medical study of the disease and its prevention, and Dr Parker's letter (BRITISH MEDICAL JOURNAL, August 27th, p 366) seems to me to smack just a little of *laissez faire*. Whatever one's views may be as to the exact relation between tonsillitis and rheumatism, there can be little doubt as to the closeness and importance of the relation, and it follows that the most crucial part of the prevention of rheumatism from the medical point of view is the prevention of tonsillitis. To preserve a healthy nasopharynx should be the ideal, attainment of which would help to prevent a whole host of diseases besides rheumatism. The attainment is admittedly not easy, and demands a much more serious view of the common respiratory affections of infancy than is usually taken. The ordinary "nasal discharge"—which is often regarded with complacency even by medical men—if allowed to persist lays the foundation for chronic lymphatic enlargement in the nasopharynx, with all its train of evils. Infant welfare activities should do much to improve matters in this respect. Cod-liver oil both in prophylaxis and treatment is of great value, and seems preferable to the iodine mixture suggested by Dr Parker, since it not only contains plenty of iodine but also, through its vitamin content, exercises a favourable influence on calcium metabolism. Ultra-violet light will often rapidly clear up nasal catarrh in an infant.

When the tonsils and adenoid tissues are already enlarged and inflamed, the problem is one of practical politics. Social conditions must be taken into account as well as much medical. Tonsillectomy like many another surgical procedure is a reproach to the physician but like them is often also the wisest course to adopt. It is clear that it is to restore the damaged tissue to health and function is the most desirable end and, given good hygienic circumstances, this may, no doubt, be not infrequently attained, as Dr. Puharman says. Unfortunately it is just in the "rheumatic" cases that it is most difficult to attain. In my work in the nose and throat department of the Aberdeen Dispensary I made a practice of attempting conservative treatment whenever there seems to be some prospect of success. In the great majority of the cases one is forced eventually to resort to tonsillectomy. What has to be borne in mind when considering the treatment of enlarged and inflamed tonsils is that they either are already or may easily become the permanent habitation of colonies of specific or non specific bacteria, thus composing the prolegomena to many tragedies of disease. Only when there seems to be a fairly good prospect of restoring the glands to health and function is one justified in persisting for any length of time with conservative treatment—I am, etc.

At the top of the page, the text reads: "D B C WALKER, M D, Ch B".

Sir,—In my letter in your issue of August 27th (p 366) I inadvertently cited Sir George Newman as having stated that "enlarged or inflamed tonsils are a cause (or the cause?) of rheumatism in children"

I am afraid I made the mistake—all too common—of quoting without verifying from the source the exactness or otherwiso of the words ascribed with the result that I find I have credited Sir George Newman with a view which he has never, in fact, expressed. I much regret this error and offer Sir George and yourself my sincere apology

I may add that with the exception of the first paragraph, my letter expresses my opinion on the subject under correspondence—I am, etc.,

## AN OPERATING THEATRE OUTFIT

Sm,—The timely letter of Sir John O'Connor in the JOURNAL of August 27th (p 365) opens up a question which, I submit, urgently requires to be thoroughly discussed and finally settled. Do surgeons and nurses need to envelop themselves in caps, masks, rubber glove, and "boots, gum, leg," or will the use of soap and hot water, a scrubber, and antiseptics for the hands and forearms with cleanliness of dress, (short) hair, mouth, teeth, and throat, be sufficient? I have been through the periods of (1) the Listerian ritual (2) antiseptics, (3) asepsis as practised to-day and submit that the right method is a combination of (2) and (3).

We do not need to render the patient poisoned and exhausted by a superheated theatre or by exclusion of fresh air (so-called avoidance of chill) or make ourselves uncomfortable by wrapping up as described above or by absorbing vitiated and heated air, laden with the vapour of anaesthetics. I was assistant at the South Devon and East Cornwall Hospital for many years to the late Connel Whipple, a well known Plymouth surgeon. A clean rapid and decided operator, he never took to rubber gloves (while I knew him), but wore a sterile overall and carefully prepared his hands and forearms with plenty of hot water and soap thorough scrubbing and prolonged soaking in a solution of mercury bismide in alcohol! I do not remember that he got more sepsis in his work than any of the surgeons who followed "aseptic" methods. I have been an ardent advocate of rubber gloves, but now, except for septic cases, have discarded them. From age and force of circumstances I perform no major operations at present but I do all the minor surgery that comes my way with cleanliness and strict attention to antisepsis detail. In the only case of mine which became infected, two years ago, I made use of rubber gloves—I will etc

## CONVULSIONS OCCURRING DURING SURGICAL ANAESTHESIA

Sir—I do not think Dr Pinon (Nw Leth, p 256) has to look for the cause of his trouble it was in the too large doses of atropine that he has been employing in conjunction with ether anaesthesia. The ether was in no way to blame. The majority of medical men fail to realize that the same dose of a drug cannot be given to a patient when under an anaesthetic as can be employed with possible safety in a patient who is not under that influence it depends upon the anaesthetic used. In other words Dr Pinson might have given, say 1/60 grain atropine to a patient and used chloroform as his anaesthetic and not had death shivers with the same patient if he had used ether he would have had convulsions and possible death.

During my thirty years as an anaesthetist and a teacher of anaesthetics I have spent some years working out the correct dose of morphine and atropine to be given to any patient prior to operation. The correct dose—that is, from the point of view of absolute safety and also I have no hesitation in saying the routine and maximum dose for any patient over 12 years of age should not exceed 1/8 grain morphine and 1/150 grain atropine. Between the ages of 5 and 12 years the dose should be 1/12 grain morphine and 1/200 grain atropine. The doses mean safety and are ample for all patients male or female. The symptoms of atropine poisoning are: Convulsions followed by paralysis, pupal at times alternating with delirium, coma and death preceded by heart failure and failure of respiration. Death is due to asphyxia"—I am, etc.,

Melbourne July 6<sup>th</sup>

R W HOPKINS

Sir,—I was much interested in Dr K B Pinnore's article (May 28th, 1927, p 956) dealing with cases of convulsions occurring during surgical anaesthesia. I notice that all the cases reported by him happened when ether was used as the anaesthetic. In 1919, when I was working at the Civil Hospital, Basrah I had a similar experience, but in this instance chloroform was the anaesthetic employed. The patient was an Arab woman and the operation curettage. The anaesthetic was pure chloroform (ether or mixtures were found to be too volatile in the high temperatures prevailing) and was administered by an Indian sub-assistant surgeon. The patient went under quite well but just as I was about to begin she had a typical epileptiform fit. There was no obstruction to the breathing and no change of colour. The anaesthetic was continued, and after a few minutes the convulsion ceased and I was able to complete the operation. There were no further convulsions. I could obtain no history of previous fits.

The case completely puzzled me, seeing that chloroform is so frequently used to control convulsion. Evidently, as Dr. Pinon remarks, the anesthetic agent is not the cause, and his suggestion of an excess of CO<sub>2</sub> seems to be the only explanation—I am etc.

## A FORGOTTEN BENEFactor

SM,—It is about a great medical pioneer and about his forgotten and neglected grave that I venture to appeal for the sympathy and support of your reader.

the sympathy and support of your readers.

On January 27th, 1860, was born at Ludlow in the parish of Bromfield a picturesque village two miles or so from Ludlow in Shropshire a boy to whom the name was given of Henry Hill Hickman. Three years later on April 2nd, 1863, he died - of a broken heart - and his body was laid to rest near the grave of his grandfather in the churchyard of Bromfield. Henry Hill Hickman is now only just decipherable as he lay there and his face bore a sadly neglected appearance. He was the possessor of a broken heart for that is a common lot of poor men and a pioneer he undoubtedly was. The aged were surprised in his own day he was the real first discoverer of one of its greatest boons ever conferred on suffering humanity - the anaesthetic relief of pain. It was probably in his latter days, or whilst as the custom of radical men of that day, he was serving his time as an apothecary apprentice,

that Hickman began to feel his way experimentally towards the scientific use of anaesthesia. The principle of his method was to induce unconsciousness by inhalation. The vapour he used was probably carbonic acid gas (CO<sub>2</sub>), unmedicated. His method was no doubt crude, and probably dangerous also, inasmuch as he proposed to deprive the patient of air and put him to asphyxiate him. Nevertheless, Hickman's was the pioneer work in this great discovery. He took the diploma of M.R.C.S. and began his career as a country practitioner.

It must have been some twenty years before ether was introduced into England from America, in 1846, and still longer before Simpson in Edinburgh, three years later, discovered chloroform, that Hickman was trying in vain to get his anaesthetic discoveries recognized by the medical profession. In London he could get no hearing. In Paris they gave him a warmer reception, and many encouraging words. He even secured the honour of an introduction to the French King, Charles X, but neither in France nor in his own country could this young surgeon get any practical move on in the way of specialized experimental research. Having by this time a wife and children he had to revert to the ordinary ways of earning his livelihood. For a while he practised in Shifnal, in Ludlow, his native district, and in Tenbury. At the latter place he lived at No. 18, Teme Street. A notice card is still extant to say that on every Tuesday (the market day in that town) he was willing to see gratis, between certain hours, the poorer people of the neighbourhood. Was this kind yet eager heart already beginning to break? Anyhow, at the early age of 30 he died at Tenbury, leaving a widow and four children.

At the beginning of the present century Hickman's name was partly recovered from obscurity by one or two of the leading medical journals, and some little honour was done to his memory. Mr C. J. S. Thompson, a chemical authority, wrote a long and interesting article on Hickman's short and tragic career in the *BRITISH MEDICAL JOURNAL*, April 13th, 1912 (p. 843). It was illustrated by Hickman's portrait—a very pleasing one, in the possession of his granddaughter—from a copy in the Wollecome Historical Medical Museum, 54, Wigmore Street. All this took place just before the outbreak of the great war. That catastrophe overshadowed, of course, greater events than the revival of any one individual memory. Now that we are coming back to more normal times, and now that we are nearing the centenary of Hickman's death, is it not reasonable to hope that those who represent the English medical faculty will do something to recognize the debt which we all owe to one of our greatest medical pioneers? The least that might be done is that his dilapidated grave-stone should be restored, with some suitable inscription perpetuating his name, and expressing the honour long overdue to a great human benefactor, one with English blood and English bred—I am, etc.,

F. WYLAND JOYCE,

Formerly Vicar of Harrow and Prebendary of St Paul's

Petersham Aug 20th

### ULTRA-VIOLET RADIATION AND VARICOSE ULCERS

SIR,—In the discussion on the uses and limitations of ultra-violet radiation in the Section of Dermatology at the Annual Meeting of the British Medical Association, Dr F. Gardiner is reported to have stated, "It was useless for varicose and chronic ulcers" (*BRITISH MEDICAL JOURNAL*, August 13th, p. 257). This statement, in the present stage of the development of actinotherapy, is unduly dogmatic and, coming from an authority who has obtained good results with ultra-violet treatment in such difficult conditions as lupus erythematosus and syphilis, carries too much weight.

It will be observed that Dr Dore, who read the opening paper in an admittedly pessimistic vein, stated that chronic septic and tuberculous ulcers are benefited by light. It is assumed that he included varicose ulcers in this chronic septic type.

These two opinions, coming from accepted authorities, would have been irreconcilable if Dr Gardiner himself had not given the explanation by saying, "The accurate and scientific dosage and the limitations of the new therapy could not yet be stated." Throughout the discussion and, it may be added, throughout the literature on ultra-violet treatment, these diametrically opposed views are continually met with. The reason, of course, is that there is no standard technique, and unless the technique is mentioned there is no common ground for discussion. Ultra-violet treatment may mean a few minutes with a carbon arc at three or four feet, or double the time with a Kromayer in contact.

I have not found ultra-violet radiation useless in the treatment of varicose and chronic ulcers but, on the contrary, very valuable. Varicose and other ulcers which had remained unhealed for many years, in spite of every form of treatment, immediately began to improve, and steadily healed with ultra-violet radiation—I am, etc.,

London, W. 1, Aug 18th

M. WEINBERG.

### BLOOD PRESSURE

SIR,—Many members of the medical profession will feel grateful to Dr Adam Moss for his letter on blood pressure which appeared in your issue of August 20th (p. 328). In it he states what must have passed through the minds of many of us. What he objects to is unfortunately, only one of several practices which, under the name of medical or surgical advances, are used without due regard to the real advantage of the patient—I am, etc.,

JOHN CAMPBELL, M.D.  
F.R.C.S. Eng.

Craigavad Co. Down, Aug 30th

### Medico-Legal.

#### ACTION TO RECOVER MEDICAL FEES

Our special correspondent in Capetown sends the following note. A decision of much interest to the medical profession in general and to specialists in particular, was given in the magistrate's court, Wynberg, on July 5th, by Mr D. D. Leslie, A.R.M., in the action brought by Mr C. E. Jones Philipson, F.R.C.S. Ed., of Capetown, against Otto Thiel. The plaintiff, who practises as an ear, nose, and throat specialist, sued the defendant for the sum of twelve guineas, being professional fees for services rendered to the latter's daughter. Defendant denied responsibility claiming that he was not in law liable for the fees—his daughter being a minor—and that, in any case, they were excessive and unreasonable. He conducted his own defence. According to the evidence of plaintiff, Mrs Thiel consulted him one afternoon, complaining of great pain in the ear. The trouble was diagnosed as inflammation of the middle ear. He applied immediate treatment for alleviation of the pain, and sent her home with instructions to report to him on the following day. After her departure, in accordance with a well established custom in the profession, he communicated with the girl's mother on the telephone and explained the position, giving at the same time instructions as to further treatment. Mr Thiel was not at home at the time, and plaintiff did not speak to him about the case. Mrs Thiel attended at his consulting rooms six times in all. His fees for the consultations and treatment amounted to twelve guineas, an account for which was rendered in due course. Evidence for the plaintiff was given by Dr W. Duley Hunter, President of the Medical Council, who asserted that the procedure adopted by Mr Jones Philipson in communicating with the mother of the patient who was a minor, was correct. It was not usual, he declared, to discuss the question of fees beforehand, and the fees charged, in his opinion, were most reasonable. Evidence testifying to the correctness of the treatment advised and to plaintiff's observance of medical etiquette was given by Mr H. A. Moffat, F.R.C.S. and Mr F. F. Petersen, F.R.C.S. Ed. Called by her father, Mrs Thiel stated that she had been troubled by earache, and had been advised to consult Mr Jones Philipson. She was not aware of the fact that he was a specialist when she went to him and her father knew nothing about the visits until later. Cross-examined, she admitted that her trouble was relieved as the result of the treatment received. After hearing counsel in result, the magistrate granted judgment for plaintiff, with argument. He found that the treatment had been necessary, that costs incurred had been essential and that the ear trouble was such as reasonably to require the services of a specialist. He was further of opinion that Mr Jones Philipson had acted in accordance with professional custom in communicating with the girl's mother, and that the fee charged was, for a specialist, in no way excessive. The only other question was whether, in the circumstances, the mother of the minor was in law liable to pay, which question had to be answered in the affirmative.

## Obituary

ALBAN HENRY GRIFFITHS DORAN F.R.C.S.F.R.C.,  
Consulting Surgeon to the Samaritan Free Hospital  
London

In an announcement in our issue of August 20th we regretfully stated that Mr Alban Doran had been admitted to the ophthalmic ward in St Bartholomew's Hospital suffering from acute glaucoma notwithstanding all that the loving care of the staff of his old hospital could do for him he died on August 23rd.

In the London medical world he was once a familiar figure which however, had not often been seen lately, as advancing years and failing sight restricted his activities. Twenty or thirty years ago Alban Doran's personality, his anatomical and general medical erudition and certain harmless eccentricities of movement and expression marked him out for notice at those meetings of medical societies which he long frequented where his small but active figure and his alert carriage never failed to attract attention.

He was brought up in a literary atmosphere for his father Dr (of Philosophy) John Doran F.R.S. was editor of the *Athenaeum* and of *Notes and Queries*, and was the well known author of various works on the stage and historical subjects.

Alban Henry Griffiths Doran was born in London in 1849 and received his preliminary education at a private school. He entered the medical school of St Bartholomew's Hospital in 1867 and distinguished himself by winning scholarships and prizes. After holding the office of house physician to Dr Reginald Southey and house surgeon to Mr Lutley Holden he was appointed an assistant demonstrator of anatomy in the medical school but gave up teaching after a year's experience. He obtained the diplomas of M.R.C.S. and L.S.A. in 1871 and that of F.R.C.S. in 1875. Doran was a skilled and delicate dissector and in 1875 he became anatomical assistant to Sir William Flower at the Royal College of Surgeons in England, thus beginning a connexion with its museum which lasted almost to the end of his life. Soon after this appointment Flower fell ill and in his absence Doran undertook the secretarial work of the conservator which brought him into relation with many eminent men of science such as Richard Owen, Huxley, St George Mirart Garrod, Slater (who investigated the remains of an albatross bird from Rodrigues Island) Parker Vachon and others. On the return of Sir William Flower, Doran helped him in his work of craniometry.

Doran's attention was drawn to the middle ear in mammals, and he took up the subject enthusiastically exploring the large store of mammalian skulls in the museum and finding a great number of auditory ossicles which he mounted on glass. It only then came to his knowledge that Professor Huxley had written a monograph on the subject based on a considerable number of specimens. At that time the College received frequently the bodies of animals which had died in the Zoological Gardens, and these furnished him with additional materials. With the help of Mr Ockenden for many years an assistant in the Gardens, he dissected out the

and took out of an elephant. The collection of ossicles thus required was displayed as they may still be seen in a wide shallow box. To the collection added Max Hübner's collection showing the anatomy of the bone of the inner ear in mammals, which was recounted by Mr Doran. The ossicles audited were exhibited at a meeting of the Royal Society and a little later a monograph on the subject was published with engravings by Bergeau, in the *Transactions of the Linnean Society* (1878).

But Alban Doran's industry and intelligence were not exclusively devoted to anatomy. He held the appointment for some years of pathological assistant at the College of Surgeons, and for eight years he laboured with Sir James Paget and Sir James Coddart in the compilation of a catalogue of the pathological specimens in the museum. In 1877 he was elected an assistant surgeon to the Samaritan Free Hospital for Women where he had Sir

Spencer Wells, Dr Bantock and Mr Knowles Thornton for colleagues and took part in that development of gynaecology with which his names and his own will always be associated. For eight years he acted as president in the arrangement of the surgical series of the pathological collection at the College of Surgeons and his practical knowledge was of great value in the rearrangement and description of the specimens illustrating disease and injury of the female genital tract, many of which were obtained from the Samaritan Hospital. Doran worked for thirty-three years at the hospital his surgical operative work being largely concerned with supracervical hysterectomy for fibroid and with certain abdominal tumours mainly retroperitoneal the pathology and the operative results he brought before various societies and published in this Journal.

When he retired from private practice in 1909 Doran returned as a volunteer worker to the museum of the College of Surgeons where Sir Arthur Keith afforded him facilities for work in any field that he preferred. The

obstetrical and gynaecological series were there rearranged with the valuable help of Professor Slater and he obtained the aid of Dr Barr and Sir Bartholomew's Hospital in mounting a small but instructive group of normal and deformed pelvises.

Doran had become President of the Obstetrical Society in 1899 and when that society was abolished by the Royal Society of Medicine he used his influence to promote a transfer of its museum as a loan collection to the College of Surgeons and from 1912 onwards he was largely devoted to the compilation of a descriptive catalogue of the obstetrical and other specimens in the museum to which Sir Pickman Godlee added his appliances and instruments used by Lister in his physiological and pathological researches and in the evolution of the puerperal emergency. Doran completed the descriptive catalogue before he died in 1915. It has been typed and many of the plates printed and it forms a handsome work of 1000 pages. It is not quite unique or his industry and knowledge would be understood that the catalogue is being prepared by Mr C. S. Thompson lately of the Wellcome Historical Medical Museum, who had helped Mr Doran in the carrying out of his compilation.

*Alban Doran*

Doran joined the salaried staff of the *BRITISH MEDICAL JOURNAL* as sub-editor in the early eighties, when Mr. Lincolt Hart was the editor, and Dr. Alexander Henry, who had long been secretary of the Metropolitan Counties Branch, was assistant editor, the other sub-editors were Dr. Faucomt Barnes, son of the more famous Dr. Robert Barnes and Mr. George Eistes, F.R.C.S., who had been honorary secretary, and afterwards treasurer, of the Metropolitan Counties Branch, and subsequently an active member of the central Council. The salaries were small and the duties light, but Doran would spend the whole of publishing day with Dr. Henry. He could always be depended upon to get up his facts carefully, had a command of several languages, and wrote a good English style. But journalism did not appeal to him, and he presently found more congenial occupation at the Royal College of Surgeons, as has already been related.

Alban Doran's was not a narrow mind. Notwithstanding his anatomical, pathological, and surgical activities, he found time to acquire much curious learning and a wide knowledge of literature. He was an accomplished Shakespearean scholar, and contributed the article on "medicine" to *Shakespeare's England*. Those who had the good fortune to hear his annual oration as President of the Medical Society of London in 1899 on "Shakespeare and the Medical Society" will remember with what an almost overpowering wealth of quotation it was illustrated. His article in the *Journal of Obstetrics of the British Empire* on "Burton (Dr. Slop), his forceps and his foes," in which he wrote of Dr. Burton of York and Sterne's caricature of him, displayed not only his erudition but also his sense of humour. He was an honorary fellow of several foreign societies, and besides the works above named he published a *Handbook of Gynaecological Operations* in 1887.

[The photograph reproduced is by Mr. Adolphus Tear, London and Ipswich.]

#### ARTHUR DRURY, M.B., C.M.,

Late President of the Association of Public Vaccinators

Dr. ARTHUR DRURY, who died on August 22nd, at his residence in Halifax, at the age of 66, received his medical education at Edinburgh where he graduated M.B., C.M. in 1887. He then commenced practice in Halifax and held the appointments of medical officer to the Halifax Union and public vaccinator to the borough.

Dr. Drury will chiefly be remembered for his strenuous support of vaccination, he was honorary secretary of the Jenner Society, and for a time he edited a supplement to the *Medical Officers' Journal* on this subject. He was at one time president of the Association of Public Vaccinators of England and Wales, and he was the author of an article on vaccination published in the *Journal of the Royal Sanitary Institute*. During the war he served as registrar of St. Luke's War Hospital, Halifax, with the rank of Major R.A.M.C.

Dr. Drury was assistant secretary of the Yorkshire Branch of the British Medical Association from 1890 to 1900, and a member of the Branch Council from 1909 to 1914. He was a representative of the Halifax Division from 1908 to 1916, and chairman in 1914. He was also a member of the Vaccination Subcommittee of the Public Health Committee from 1912 to 1913.

We are indebted to two of Dr. Drury's colleagues for the following personal appreciations.

Dr. A. E. COPE writes: The news of the death of Dr. Arthur Drury will come with the shock of painful surprise to many who never had the privilege of his acquaintance. Right away from the time when, in May, 1893, as public vaccinator for Halifax, he gave evidence before the Royal Commission on vaccination, his name has been closely linked with the cause he there advocated. The formation of the Association of Public Vaccinators of England and Wales naturally attracted him, and he was one of the early members, being elected to the council in 1903, and serving as president from 1907 to 1909. He threw himself most actively into the association's work, rarely missing a council meeting and his keen insight, abounding energy, and journalistic instinct deeply influenced its policy and

extended its influence. On the death of Dr. Bond of Gloucester he took over for a time the secretaryship of the Jenner Society, and held himself ready to enter the lists against any of the opponents of vaccination, whether with voice or pen. For many years he edited the supplement to the *Medical Officer*, devoted to the interests of the Association of Public Vaccinators, while more recently he added to his labours the editing of a similar supplement on behalf of the Poor Law Medical Officers' Association. Both associations will find it difficult to fill his place.

He was a keen controversialist, but never harboured a grudge, and his uncompromising honesty and singleness of aim won him friends even among his opponents. Although his health had been a source of anxiety for some time his tireless enthusiasm and indomitable courage kept him at work right to the end. He gave evidence quite recently before the Vaccination Committee appointed by Mr. Neville Chamberlain, and in July he took part in the discussion on small-pox at the Hastings meeting of the Royal Sanitary Institute. We lose a most loyal comrade and friend, and the public health service a strenuous and unselfish advocate.

Dr. JAMES BRADY writes: As ex-president of the Public Vaccinators Association I feel I must write a short appreciation of my old and sincere friend, the late Dr. Arthur Drury of Halifax. Dr. Drury was a man of magnetic personality, of the most transparent sincerity, and these, accompanied by such an extraordinary gift of expression, both by word and by pen, made him a truly outstanding figure in the great profession to which he belonged. How he spent his strength for others is well known to his medical colleagues, and in spite of physical suffering, which for several years necessitated his taking a long holiday in the South of France during the winter months, his temperament was such that he could not find peace of mind unless he was working at a rate impossible to most of us, and he died in harness, which was his wish. A brilliant debater and an incisive writer, he has rendered unmeasurable service to the community as a whole by his advocacy of vaccination for small-pox. Those of us in closest touch with the Public Vaccinators Association are only too conscious of the great loss we have sustained. Capable of almost superhuman effort and accomplishment, and giving unstintingly of his brilliant qualities, his place can never be adequately filled by one person. Notwithstanding that his sight had all but failed him, and his strength had ebbed, he was as cheery as ever and arranged to attend the congress of the Royal Sanitary Institute at Hastings, to support the case for vaccination. Few men possessed such a knowledge of the history of small-pox, combined with statistics relative to the efficacy of vaccination. It is therefore little wonder that when legislative changes were contemplated his experience was so frequently drawn upon. His was a case of "the busy man always finding time," for not only had he built up a large private practice, but the causes of Poor Law and national health insurance always found in him an able exponent and a faithful practitioner.

Dr. SAMUEL WILLIAMS, who died at his residence in Llanelly on August 19th, aged 60, received his medical education at Cardiff and University College Hospital. He obtained the diplomas M.R.C.S. Eng., L.R.C.P. Lond. in 1891, graduated M.B. Lond. in 1893, and proceeded M.D. two years later. He held the appointments of house-physician and obstetric assistant at University College Hospital, and was later senior medical officer at the City Fever Hospital, Birmingham. For some time subsequently he travelled abroad and then commenced at Llanelly an eminently successful practice, taking a prominent part in the medical affairs of the district. He was a member of the Executive Committee of the South-West Wales Division of the British Medical Association from 1907 to 1913 and from 1922 to 1925. He was a member of the South Wales and Monmouthshire Branch Council in 1914 and chairman of the South Wales Division in 1916. He was also secretary of the Panel Committee a certifying surgeon under the Factory Act, a medical referee under the Workmen's Compensation Act, and during

### QUERIES AND ANSWERS

#### DIAPHORETICS AND DIURETICS

"**SCRUTATOR**" finds that many diaphoretic and diuretic mixtures are unpalatable. He asks for suggestions as to mixtures which are at once palatable, effective, and reasonable in cost.

#### HYPERIDROSIS

**Dr C. J. L. Cook** (Blackheath) writes in reply to "**Tropicus**" (*JOURNAL*, August 27th p. 372): "I would suggest he tries an ointment containing 2 per cent of formaldehyde in hand without previous bathing by the patient. This is rubbed once a day into the feet and hands on two or three extreme cases on three or four successive days after which the hyperidrosis ceases and the sweat is brought back to normal. The effect lasts from four to six weeks, when the treatment may be repeated, if necessary."

#### OMENTAL TEARS

**Dr JOHN M. MUNRO** (Odessa, Ontario) writes in reply to "**M.B.**" (*Ch.B.* July 23rd p. 152): "The case seems to be one of 'tear on the omentum.' An exploratory operation is necessary to relieve the pain as the omentum may be caught in the tear. I had a case recently and on operation found the omentum not only caught but herniated to such an extent that it could not be replaced in the abdomen without extension of the tear, and then a kangaroo tendon suture to close."

#### TREATMENT OF ONYCHIA

**Dr AGNES SAVILL** (London, W.) writes in reply to "**W. S. M.**" (*JOURNAL* July 30th p. 196): "Onychia is so obstinate that every means of raising the general resistance should be employed. Fresh air, tonic, vaccines, sunlight, exercise, plenty of water, fruit, vegetables, and avoidance of sweet foods all aid the patient. Locally mild mercurial ointments may be sufficient, but ionization provides the most reliable means of dealing with the infection. A small piece of gauze or cotton wool soaked in a 2 per cent solution of zinc sulphate is carefully inserted round the base of the nail, another piece is placed over it and a small flexible tin electrode attached to the positive pole. The negative pole is a larger pad on the anterior aspect of the forearm. A small current—1 to 5 milliamperes—is passed for five to eight minutes according to the severity of the condition. Three or four applications given twice a week are usually sufficient even in severe cases."

#### ANGIO-NEUROTIC OEDIMA

"**C. F. S.**" who noticed the inquiry of "**Ajax**" (*JOURNAL*, August 20th p. 331) as to the treatment of a case of angio-neurotic oedema asks whether the administration of fresh sea water has been tried. "**C. F. S.**" suggests that "**Ajax**" might begin with doses of 5j in water two or three times daily, half an hour before food, increasing the amount up to one half or one pint in the twenty-four hours, if necessary. It is readily taken by infants in milk or when they have come to appreciate its pleasant "ting" in plain water. It does not retain its energizing, soothing and vitalizing properties for more than about a week, but the tuberculous child the weak and overworked adult the asphyxiated and in all septic cases however severe its action and its virtues so widely recognized and used more than two centuries ago should have been for so long forgotten. Even its

effects in miasmas neonatorum (made known to us by the French some fifty years since)—peace in twenty-four hours, plumpness and happy activity by the end of another four or five days at the most—do not seem to be remembered.

### LETTERS, NOTES, ETC.

#### TOLAFRIA AND MENTAL DISORDER

**Dr JOHN B. BIRNY** (Keshelagh) writes: "I was asked to see a young woman with a view to her readmission to an asylum for the third time. On entering the bedroom I was impressed by the disgusting odour, which I found was due to the state of the patient's mouth. She had eyes and mouth closed, and appeared almost unconscious. I decided to treat the mouth, and, if possible, get rid of the bad smell before sending her away. I procured a 2 oz. glass syringe and making a wash of one part of hydrogen peroxide to seven of warm water, gave the mouth and throat a good wash out, this treatment was followed up every four hours by the mother until the next day, by which time not only was the offensive smell almost gone, but the girl was taking notice and able to swallow liquid nourishment. When I visited her on the third day she was downstairs by the fireside, and it was not necessary to send her to the asylum."

#### RHEUMATIC INFECTION IN CHILDHOOD

**Dr A. C. T. HALFORD** (Brisbane, Australia) has been induced by the leading article on the prevention and control of infection in childhood, published in our issue of April 16th last (p. 731), to send a letter, too long and discursive for publication in full, expressing his conviction that rheumatic infection can be conveyed from one person to another. The concluding part of his letter contains the following passages: "In my own practice a large proportion of cases show evidence of pre-existing disease in parent or guardian, though persistent inquiry and clinical examination has had to be resorted to to establish a positive or a negative history. Acute rheumatic affections in the child are sometimes overlooked by the medical attendant, and these cases go to swell the number of negative histories. I therefore believe that the disease, like phthisis, is conveyed from a previous case as a result of exposure to infection on innumerable occasions over the long period of childhood. It is evident that prevention depends upon a careful survey of those in whose case we find the sufferer. A proper clinical examination in every case may reveal in the parents factors which ultimately may be found of great import. All focal infections must be regarded with the same suspicion as sources of danger to others as they are now regarded as unfavourable to the host. The influence of mixed infections is baffling and must be guarded against among all in the household and these persons should be warned that the disease itself is communicable. The power of the infection to be latent, ohemic, and practically forgotten is seen most convincingly in the recurrences in the same patient at long intervals. It is impossible, therefore, at any time, to declare a patient free from infection. Why not regard a parent with or without an incriminating history as suspect in the same manner? In both instances there are dangers to others. Why not guard against such possibilities?"

#### TRIATAMINI OF VARICOSE VEINS BY INJECTION

**Dr S. M. WILLS** (London) writes with reference to Major General T. M. Corbier's inquiry, that within the last year he has treated about twenty cases in Valparaiso all—except one of which he does not know the sequel—with very good results. He heard of no accidents in the case of colleagues. He adds: "The injection, no doubt, causes an aseptic phlebitis and a firm thrombosis in the veins. After the injections there is some redness and tenderness, which causes a little inconvenience. The injection can be given in the consulting room and the patients can go about their work as usual immediately afterwards. Varicose ulcers clear up in a comparatively short time. Those who complain of heaviness and tiredness in their legs are greatly relieved. One of my first cases a lady, had extensive varicose veins reaching well above the knees and a very painful varicose ulcer in the usual place, about the size of a shilling. She could not afford to lie up, having a family of eight, and she did the morning housework, she obtained relief after the first injection, the ulcer ceased to hurt her, and she was able to go about quite well. The ulcer healed over in a little more than a month. The veins could be felt like cords under the skin, and there was no tenderness anywhere. I usually give two to three injections at about three to four inches interval at one sitting, repeating the process in a week wherever the veins are soft, this is not the case round the site of previous injections. The average case requires about three sessions. Of my cases three had ulcers, two healed completely to my knowledge. The third had just finished treatment when I left. The ulcer was smaller and had shelling, not punched out, edges, it was covered with healthy granulations and quite painless. All the patients were highly pleased with the method and consequent benefit, since they did not have the loss of time, discomfort, expense, and ever present danger of a surgical operation."

#### VACANCIES

**NOTIFICATIONS** of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 36, 37, 38, 39, 42 and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenures at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 128.

# THE TREATMENT OF ACUTE LOBAR PNEUMONIA

## I—PROPHYLAXIS SPECIFIC TREATMENT: SYMPTOMATIC TREATMENT

JOHN HAY, M.D., I.R.C.P.,  
Prof. of Medicine University of Liverpool

The question of the treatment of patients suffering from pneumonia is one of paramount importance, and one which appeals to every member of our profession. I realize not only the honour but also the responsibility of being asked to speak in the open, and my remarks will be directed with the object of promoting and exciting a full and free discussion, rather than of urging any particular view or views which I may hold.

Pneumonia is a disease which killed 35,930 persons in England and Wales in 1925, and if we accept a mortality of 20 per cent there was a severe incidence of 185,000. In the city of Liverpool, with a population of 842,268 in one year there were 640 deaths, 3,200 persons were affected, or 1 in every 263 of the population.

It is remarkable that even to-day there is no immunity as to the actual nature of the disease. It is admittedly an infection, and the causal organism is the pneumococcus, either alone or in combination with other organisms acting as allies in its attack on the patient, but what is not agreed upon is the method by which infection takes place.

As we consider it a primary blood infection, a septæmia or is it a disease invading the lungs directly by way of the air passages? In other words, is it to be considered of hæmatogenous or biologically origin? This is a question of considerable importance when one comes to discuss the question of specific treatment.

The drift of opinion is away from the conception that pneumonia is primarily a general infection and towards the view that it is entirely a local infection striving to become general. Accepting the second view, we may say that pneumonia is a specific infectious disease due to the pneumococcus with the primary site of infection in the lungs.

The outlook in any particular case depends on the virulence and type of the infection and the local and general resistance of the patient. The infecting pneumococcus may belong to one of four groups.

Professor E. L. Glenn has pooled the American and British figures. His figures show the relative incidence of the types and the associated mortality.

Type 1	In nearly 1/3 of adults	25%
Type 2	In nearly 1/4	33%
Type 3	In nearly 1/10	50%
Type 4	In more than 1/4	10%

In addition to the pneumococcus, among other organisms the streptococcus or influenza bacillus may be present.

Pneumonic patients seem to have had a bad time in the past. In the early part of the nineteenth century they were excessively purged, bled and starved. Later on, alternatively, they were treated with massive doses of nauseating antimony, and, still later, they were drenched with alcohol. The mortality was appalling, and by degrees it was recognized that treatment less dramatic and more imbued with common sense gave far better results.

Pneumonia is a self-limiting disease tending to recovery. In 100 cases the chances are that about 75 will survive if allowed to do so. 10 to 15 will probably die—doomed from the first. This leaves another 10 to 15 patients who are chances or recovery will depend on the manner in which the case is handled. The medical man is the determining factor in this small percentage of patients. Correct treatment and careful nursing are going to turn the balance.

For the last few years there has been an earnest endeavour to discover some treatment which might fairly

be called "specific." But of a specific comparable in result to the antitoxin for diphtheria or a vaccine comparable to that I cannot find in the literature. We are arrested by the preliminary facts before we reach the infectious disease in which treatment becomes a recognized and assured position. If the medical man drenches pneumonia with the first acute infection to be combated successfully in this way.

### Prophylaxis

Pneumonia is an infectious disease and prophylaxis in regard to it obtains less consideration than in diseases.

In view of its contagiousness it is unwise to concentrate the pneumonia as in a general ward of a hospital. In 1883 I made this mistake in order to facilitate chemotherapy with the unfortunate result that three of the out-patients developed pneumonia.

When a patient suffering from pneumonia is nursed in a general ward he should be partially screened off from the adjacent patient. Sputum should be disinfected as well as clothing and other fabrics which have been contaminated by the patient.

Every nurse should be taught to hold a disinfectant paper over the nose and mouth of the patient when he coughs or sneezes.

Examining the right side of the patient's head is essential. The patient may and must be left and vice versa. Otherwise the patient may and must be left, cough directly into the face of the doctor or nurse. It is not only unpleasant but clearly dangerous.

Hands should be washed after examining a patient and always before food is taken.

Since the pneumococcus is liable to lurk in the mouth of the patient, attendance on the patient requiring with caution or other anti-septic is advisable.

Finally, the room should be carefully scrubbed down and the bedding disinfected when the illness is over.

**Prophylactic Vaccination.**—This is no longer a matter for controversy of uncertain value. Since 1911 the evidence has been accumulating and the result of prophylactic vaccination in the mines of South Africa in which it is used by Sir John Lister has proved that the administration of large doses of pneumococcus has a specific effect and greatly diminishes both the incidence of the disease and its mortality. The great value of prophylactic vaccination has been further demonstrated by Cecil Auer, Vaughan and others. However, there is no treatment practicable in ordinary life if a fresh attack occurs but it is certainly advisable in the case of those nursing pneumonia and in the case of men in the army or in the navy or in the work are frequently and inevitably exposed to the disease in close quarters. The risk of an outbreak of pneumonia is lessened. The nature of the disease is variable in extent with the prevailing type of infection.

Pneumonia has been anticipated as a general emergency and from the onset there is a rapid and early manifestation. It may be treated as a general disease. While much more could be said in regard to this, in private, the essentials are the same.

In private you will be surrounded by nursing friends and friends. The suddenness of the onset of the disease in the confinement of the patient gives rise to complications between hope and despair. The atmosphere of apprehension is not only a burden to the patient but also a burden to the doctor. It is difficult to judge the trend of the disease in the early stages. The tendency is to over-estimate the danger to the patient and to his relatives in mind or whom it affects. It is a term for which there is no doubt the disease is a general emergency. For the sake of the patient and perhaps of the doctor, it is better to err on the side of which he has said that the disease is a general emergency. Confidence and calmness are essential. The doctor—the man responsible for the patient's life.

The common rule of the doctor is to keep the patient in bed and complication is avoided or minimized. The three important factors are (1) to maintain (2) to avoid (3) to keep the patient in bed. The result of the patient's life is the same. (1380)

For treatment to be effective, therefore, these factors must be borne in mind from the first. The main essentials are fresh air and complete physical and mental rest. A quiet, cool, well ventilated room, with an open window—for fresh air is a tonic. A fire, but no fire. The bed should be single, the bed clothing light, there should be neither cold nor too dense counterpane. No gungsee jacket is required. A gungsee jacket is merely a sop to the mentality of the relatives and nurses.

The clothing should be loose and open down the front to facilitate examination. It is then easy to examine the major part of both lungs without disturbing or distressing the patient. With arms at rest on the pillow above the patient's head there is easy access to the axillae. After a diagnosis has been made this method of examination will suffice.

From the first the need for absolute rest must be impressed on those in attendance, and the use of the bed-pin, distasteful as it is to some, must be insisted on from the beginning. Every unnecessary movement should be avoided, energy must be conserved. The time to treat eridne fulure is before it has occurred. If, however, the patient is comfortable in the semi-prone position there is no reason why he should not be partially propped up. Sometimes breathing is easier thus. Tepid sponging is soothing, and tends to ease and comfort, and is standing to the vasomotor system.

A pneumonic patient is thirsty rather than hungry. He should have plenty of fluid, and in the first forty-eight hours fluid only, water, or natural lemonade containing glucose, diluted fruit juices, grapes, and one pint of milk in the twenty-four hours, well diluted. Tea or coffee may be given but the coffee should not be allowed towards the end of the day. After the shock of onset (in a mild case) there is no objection to a somewhat less sloppy diet—such as a lightly boiled egg, pines, and a few dry biscuits. I question whether it is wise to give soups and broths.

At the onset the bowels should be freely opened. Calomel or salines, or a combination of both are generally all that is required. If the bowels are stubborn, then a simple enema. This can be repeated when necessary, or a saline given each morning.

**Abdomen**—Throughout the illness the condition of the abdomen must be carefully noted, and at the first indication of distension steps taken to afford relief. A distended abdomen hampers the diaphragm, and in emphysematous patients or those with old-standing mitral disease abdominal distension is a grave complication. If there is reason to suspect that the diet is responsible then milk should be stopped, sugar diminished, a simple enema given, and, if necessary, a rectal tube inserted to remove colon flatus. If these measures fail, an intramuscular injection of pituitin should be given. An ice-bag to the abdomen is sometimes of service.

#### Specific Treatment

We now come to consider specific treatment—treatment by vaccines or serums or both, a line of attack concerning which there is undoubtedly considerable difference of opinion. For example, in the 1925 edition of Osler's *Medicine* we read that "There is no proof that the use of vaccines is of value in treatment." And in the article by Drs R. A. Young and G. E. Barnum contributed to the textbook edited by Dr F. W. Price, the position is summed up thus: "Vaccine treatment is recommended by some, but the results are generally disappointing during the acute stage. Vaccines seem to be more valuable in cases of delayed resolution." This may be taken as fairly representing the view of the majority of the profession in regard to the use of vaccines in the treatment of pneumonia.

On the other hand a large amount of careful work has been carried out which tends to show that, under certain limited conditions in which types of the disease, vaccine treatment does shorten the illness, modify the severity of the attack and diminish the mortality. In England Professor Wynn is well known for his enthusiastic advocacy of this form of treatment.

My personal attitude towards the therapeutic value of vaccines in pneumonia has been frankly critical. I looked upon pneumonia as a septicaemia in which there is, as a rule, a good morrow response with an adequate leucocytosis, and serum treatment (when feasible) appeared to be the line of attack most likely to give results. In addition, I was perhaps unduly influenced by the practical difficulty in determining the specific form of organism responsible in each patient, and the delay in preparing an autogenous vaccine.

Recent investigations, however, seem to indicate that pneumonia is a local infection in the lungs with only a tendency to septicaemia—in fact, a focal type of disease in which vaccines might be expected to prove beneficial and aid in the more rapid development of antibodies. I was impressed by an interesting paper published by Captain Malone in 1925, in which he dealt with 58 cases of pneumonia—29 treated with vaccines and 29 as controls. He gave a dose of 400 million on the day of admission. This was a mixed vaccine containing Type 1 (one strain) and Type 4 (three to four strains). The sputum was typed the same day and a vaccine prepared from the peritoneal cavity of a young rabbit. The next day and the day following the patients received 400 million of homologous vaccine. The results were favorable and appeared to justify the following conclusions: (1) That early vaccine treatment proved effective in promoting recovery, lessening the duration of the fever, and assisted in ending the fever by crisis. (2) That vaccines after the third day proved ineffectual. This and other credible evidence cannot be disregarded.

All the advocates of vaccine therapy in pneumonia stress the importance of vaccination within the first three days. After the third day it is questionable whether anything is to be gained by this form of specific treatment.

Pure pneumococcal pneumonia with frank leucocytosis is not clinically comparable to the influenza pneumonia, in which there is a tendency to poor or delayed morrow response, and a leucopenia rather than a leucocytosis. In these patients my treatment which will stir up the morrow is of benefit. Polyvalent serums, either antipneumococcal or antistreptococcal, protein shock, in whatever way produced, and vaccines, autogenous or stock, act in this manner. It is an open question as to how far this treatment is truly specific. This is a question for the bacteriologists.

It is in the leucopenic type of pneumonia that we should expect the best results from injections of sodium nucleinate—advocated by Dr Grindley-Medwin—during which has proved of considerable benefit.

The use of vaccines or serums is attended by certain obvious difficulties, the chief being the necessity for the active co-operation of a good laboratory near at hand, for the type of the infecting pneumococcus and also the nature or any associated organisms must be determined rapidly.

If serum is used there is in addition the very considerable expense entailed. Serum is dear and, to be effective, large quantities must be injected every eight to twelve hours. There is the liability to anaphylactic reactions (Thomas records two deaths). Serum treatment is confined to Type 1 pneumonia, but since there were in England and Wales in 1915 something like 32,000 cases of this form of pneumonia, with 8,000 deaths, there is plenty of scope for its use. These are material disadvantages, and unless the results are incontrovertible I question whether the general practitioner is likely to be an enthusiastic exponent of serum treatment. These difficulties are met to some extent, so far as vaccine treatment is concerned, by the use of stock vaccines, prepared from fresh cultures representing the putative flora of the prevailing epidemic. The stock can be used for the first injections while the pneumococcus is being typed and an autogenous vaccine is prepared. If the autogenous vaccine is not used during the acute stage it may be of service later, if resolution is delayed.

In conclusion, Type 1 serum appears to have made good in the treatment of Type 1 pneumonia, and it is possible that it may be of benefit to patients suffering from other types. To be efficient it must be injected intravenously in doses of 100 c.c. every eight hours, and this treatment must be started early.

The value of vaccines is not so varied. If they are to prove effective they must be given in the first three days and in a large dose. In practice this will generally mean the use of the vaccines.

#### Symptomatic Treatment

From specific we pass to symptomatic treatment and pain is usually the dominant symptom. Pain is incompatible with physical and mental rest, and must be mitigated. Fixation of the lower part of the chest may be all that is required but sometimes this cannot be tolerated. If the patient experiences relief when the lower chest is grasped and studied by the doctor's hands then wrapping or firm bandaging should be applied. A mustard poultice or rubbing often gives relief, but the most satisfactory method is that of a hypodermic injection of morphine, or a dose of a mixture of opium or other opiate such as Dover's powder or omnopon. So long as the analgesics are dry morphine can be given without hesitation for the relief of pain. If morphine fails as it may I should not hesitate to follow the advice of Procter or Wynn and introduce 500 to 500 c.c. of oxygen or air into the pleural cavity.

Insomnia is another dangerous symptom because of the recurrent nervous exhaustion, and it is most important that sleep should be secured in the early days of the illness before the condition is critical. Sleep must be obtained for excitable, nervous, and apprehensive patient. A cool quiet room and hydrotherapy tend to produce sleep, but may not suffice. If pain is the cause of insomnia, sleep will ensue when the pain is relieved. When in doubt, rather than risk a restless and fatiguing night, an opiate should be administered. An ounce of whiskey or brandy given as a hot drink with the opiate has a definitely soothing effect, and may prove comforting to the patient. Paraldehyde in doses of 2 drachms with an equal amount of brandy, prescribed in an emulsion in peppermint water, is another satisfactory although unpleasant, hypnotic. After the fifth day opium and its derivatives must be given cautiously, especially if there is undue secretion in the air passages. In the wild delirium, sometimes almost maniacal, which may occur at the crisis there is of course no option. Morphine, alone or combined with hyoscyamine, is the only remedy.

#### Cardiac Failure

From the first the management of the case is directed towards the prevention and treatment of cardiac failure. One factor in the production of cardiac failure is the toxæmia (always present though in varying degrees) which impairs the functioning power and the integrity of the myocardium, hits the central nervous system and interferes with vasomotor tone. A second important factor is anoxæmia. From various causes the blood flowing through the coronary arteries is deficient in oxygen. A third element is the stress on the right ventricle resulting from the pathological changes in the lung. Distension of the abdomen, with interference of the movements of the diaphragm, is a further factor which sometimes adds to the difficulties of the right heart.

From the onset management of the patient is directed towards preserving the functional integrity and efficiency of the myocardium. Vasomotor tone is maintained by hydrotherapy. The depth of the respirations is increased by cool fresh air and the relief of pain. Physical effort on the part of the patient must be reduced to a minimum. Toxæmia must be met when possible by specific treatment by careful attention to the bowels to the intake of fluids, and to the action of the kidneys.

At the first indication or evanescence the administration of oxygen should be instituted. It should be given continuously for an hour at a time and the result noted. Oxygen is probably the best cardiac stimulant. The difficulty is to get oxygen into the blood, the usual method is ineffectual and more often acts as a placebo to the relatives than as an efficient oxygenator. The funnel method is futile unless the funnel is large and applied close to the nose and mouth. More efficient is a No. 10 catheter with three to four apertures inserted into one nasal orifice after de-arterizing the mucous membrane. The other nasal orifice should be blocked with cotton wool or compressed by the

nurse during each inspiration. Recently the method does not compare with the new method. My experience is that a patient with a very poor tolerance of oxygen applied over the nose and mouth, especially if he is a particularly delicate person.

Barach (Irel Int Med 1920) and others have described an apparatus used by him with success. It is a nose-piece and rebreathing apparatus by which a 40 per cent oxygen mixture in the nasopharyngeal air is obtained. Still better results followed the use of an oxygen tent. In his opinion, the value of oxygen is supportive and not curative. It tends to prolong life until such time as the immunity mechanism is able to accomplish recovery. The passing of oxygen through alcohol is merely foolhardy. If there is considerable moisture in the air passages it is well to combine the administration of oxygen with hypodermic injections of atropine.

#### Digitalis

There is no agreed opinion as to the value or the effect of digitalis in pneumonic patients except in those in whom fibrillation existed before the onset or when it occurs during the infection. It is obvious that if pneumonia is superimposed on fibrillation the fibrillation must be controlled by digitalis, and the control maintained a daily total of 45 to 60 minims of the tincture or other adjuvant preparation must then be given from the first. Fibrillation occurring during the course of the illness must be treated in the same manner. If no member of the digitalis group has been exhibited before the onset or the fibrillation, then I should not hesitate to give an inavenous injection of strophanthin but my experience is that this toxic form of fibrillation—especially in the infarctal type of pneumonia—does not respond satisfactorily to digitalis and its allies.

In an interesting communication by Levy (Irel Int Med, September 1923) it is shown that the tendency to dilatation of the heart in pneumonia was demonstrably lessened by adequate doses of digitalis. He was dealing with hearts whose fundamental rhythm was normal. It has also been shown that digitalis has a favorable action on the efficiency of the heart irrespective of alteration in the rate. The contractility is increased.

I believe we are justified in looking upon the routine exhibition of digitalis as of value. To be efficient it should be given from the first in adequate doses—from 45 to 60 minims of the tincture in each twenty-four hour. In the short period covered by an acute pneumonia it is unlikely that any toxic effects will be produced with the above doses, nevertheless careful supervision is essential and by the fifth or sixth day the dose may require modification.

#### The Administration of Alcohol

The general public still has implicit faith in alcohol as the cardiac stimulant, and it is evident that there are some members of our profession who even now believe that alcohol in some peculiar way—in its specific action—increases the efficiency of the heart. In a recent textbook in the section dealing with pneumonia I find the following: "Alcohol is often useful. It should not be given too early in the attack but where there are indications of incipient cardiac weakness 4 to 6 oz daily may be given and this even to alcoholic." Four to six ounces of alcohol in twenty-four hours is no more than a dose.

So far no scientific evidence has been advanced in support of the view that alcohol in its specific action is a cardiac stimulant, and I am convinced that the use of alcohol in any particular patient is a very grave mistake. The doses of alcohol administered to prevent or cure cardiac failure. Like the use of digitalis in the treatment of cardiac failure, I was trained to attribute alcohol to the treatment of cardiac failure and I have seen many cases in which the result of clinical observation is that the value of the use of alcohol is not great.

In the years 1879 to 1921 I have read many papers in a large number of journals in which it was claimed that a small quantity of alcohol was a powerful cardiac stimulant and that the administration of alcohol in cardiac failure was of great benefit. For example, in 1879, 103 cases were treated without alcohol, 103 received alcohol when

For treatment to be effective, therefore, these factors must be borne in mind from the first. The main essentials are fresh air and complete physical and mental rest. A quiet, cool, well ventilated room, with an open window—for fresh air is tonic. A fire, but no rug. The bed should be single, the bed clothing light, there should be neither eiderdown nor dense counterpane. No gumboot jacket is required. [A gumboot jacket is merely a sop to the mentality of the relatives and nurses.]

The clothing should be loose and open down the front to facilitate examination. It is then easy to examine the major part of both lungs without disturbing or distressing the patient. With arms at rest on the pillow above the patient's head there is easy access to the axillae. After a diagnosis has been made this method of examination will suffice.

From the first the need for absolute rest must be impressed on those in attendance, and the use of the bed-pump, distasteful as it is to some, must be insisted on from the beginning. Every unnecessary movement should be avoided, energy must be conserved. The time to treat croup fulmo is before it has occurred. If, however, the patient is comfortable in the semi-prone position there is no reason why he should not be practically propped up. Sometimes breathing is easier thus. Tepid sponging is soothing, and tends to ease and comfort, and is stimulating to the vasomotor system.

A pneumonic patient is thirsty rather than hungry. He should have plenty of fluid, and in the first forty-eight hours fluid only, water, or natural lemonade containing glucose, diluted fruit juices, grapes, and one pint of milk in the twenty-four hours, well diluted. Tea or coffee may be given, but the coffee should not be allowed towards the end of the day. After the shock of onset (in a mild case) there is no objection to a somewhat less sloppy diet—such as a lightly boiled egg, pines, and a few dry biscuits. I question whether it is wise to give soups and broths.

At the onset the bowels should be freely opened. Calomel or salines, or a combination of both, are generally all that is required, if the bowels are stubborn, then a simple enema. This can be repeated when necessary, or a saline given each morning.

Abdomen—Throughout the illness the condition of the abdomen must be carefully noted, and at the first indication of distension steps taken to afford relief. A distended abdomen hampers the diaphragm, and in emphysematous patients or those with longstanding mitral disease abdominal distension is a grave complication. If there is reason to suspect that the diet is responsible, then milk should be stopped, sugar diminished, a simple enema given, and, if necessary, a rectal tube inserted to remove colon flatus. If these means fail, an intramuscular injection of pituitin should be given. An ice-bag to the abdomen is sometimes of service.

#### Specific Treatment

We now come to consider specific treatment—treatment by vaccines or serums or both, a line of attack concerning which there is undoubtedly considerable difference of opinion. For example, in the 1925 edition of Osler's *Medicine* we read that "There is no proof that the use of vaccines is of value in treatment." And in the article by Drs R A Young and G E Beaumont contributed to the textbook edited by Dr F W Price, the position is summed up thus: "Vaccine treatment is recommended by some, but the results are generally disappointing during the acute stage. Vaccines seem to be more valuable in cases of delayed resolution." This may be taken as fairly representing the views of the majority of the profession in regard to the use of vaccines in the treatment of pneumonia.

On the other hand, a large amount of careful work has been carried out which tends to show that, under certain limited conditions in different types of the disease, vaccine treatment does shorten the illness, modify the severity of the attack, and diminish the mortality. In England Professor Wynn is well known for his enthusiastic advocacy of this form of treatment.

My personal attitude towards the therapeutic value of vaccines in pneumonia has been frankly critical. I looked upon pneumonia as a septicaemia in which there was, as a rule, a good morrow response with an adequate leucocytosis, and serum treatment (when feasible) appeared to be the line of attack most likely to give results. In addition, I was perhaps unduly influenced by the practical difficulty in determining the specific form of organism responsible in each patient, and the delay in preparing an autogenous vaccine.

Recent investigations, however, seem to indicate that pneumonia is a local infection in the lungs with only a tendency to septicaemia—in fact, a focal type of disease in which vaccines might be expected to prove beneficial and aid in the more rapid development of antibodies. I was impressed by an interesting paper published by Captain Malone in 1925, in which he dealt with 58 cases of pneumonia—29 treated with vaccines and 29 as controls. He gave a dose of 400 million on the day of admission. This was a mixed vaccine containing Type 1 (one strain) and Type 4 (three to four strains). The sputum was typed the same day and a vaccine prepared from the peritoneal cavity of a young rabbit. The next day and the day following the patients received 400 million of homologous vaccine. The results were favourable and appeared to justify the following conclusions: (1) That early vaccine treatment proved effective in promoting recovery, lessening the duration of the fever, and assisted in ending the fever by crisis. (2) That vaccines after the third day proved ineffectual. This and other credible evidence cannot be disregarded.

All the advocates of vaccine therapy in pneumonia stress the importance of vaccination within the first three days. After the third day it is questionable whether anything is to be gained by this form of specific treatment.

Pure pneumococcal pneumonia with frank leucocytosis is not clinically comparable to the influenza pneumonias, in which there is a tendency to poor or delayed morrow response, and a leucopenia rather than a leucocytosis. In these patients any treatment which will stir up the morrow is of benefit. Polyvalent serums, either antipneumococcal or antistreptococcal, protein shock, in whatever way produced, and vaccines, autogenous or stock, act in this manner. It is an open question as to how far this treatment is truly specific. This is a question for the bacteriologists.

It is in the leucopenic type of pneumonia that we should expect the best results from injections of sodium nucleinate—advocated by Dr Grindley-Medwin—a drug which has proved of considerable benefit.

The use of vaccines or serums is attended by certain obvious difficulties, the chief being the necessity for the active co-operation of a good laboratory near at hand, for the type of the infecting pneumococcus and also the nature or any associated organisms must be determined rapidly.

If serum is used there is in addition the very considerable expense entailed. Serum is derived, to be effective, large quantities must be injected every eight to twelve hours. There is the liability to anaphylactic reactions (Thomas records two deaths). Serum treatment is confined to Type 1 pneumonia, but since there were in England and Wales in 1915 something like 32,000 cases of this form of pneumonia, with 8,000 deaths, there is plenty of scope for its use. These are material disadvantages, and unless the results are incontrovertible I question whether the general practitioner is likely to be an enthusiastic exponent of serum treatment. These difficulties are met to some extent, so far as vaccine treatment is concerned, by the use of stock vaccines, prepared from fresh cultures representing the putative flora of the prevailing epidemic. The stock can be used for the first injections while the pneumococcus is being typed and an autogenous vaccine is prepared. If the autogenous vaccine is not used during the acute stage it may be of service later, if resolution is delayed.

In conclusion, Type 1 serum appears to have made good in the treatment of Type 1 pneumonia, and it is possible that it may be of benefit to patients suffering from other types. To be efficient it must be injected intravenously in doses of 100 c.c. every eight hours, and this treatment must be started early.

The value of vaccines is not so assured. If there are to prove effective they must be given in the first three days and in massive doses. In practice this will generally mean the use of stock vaccines.

#### Symptomatic Treatment

From specific we pass to symptomatic treatment and pain is usually the dominant symptom. Pain is incompatible with physical and mental rest, and must be mitigated. Irritation of the lower part of the chest may be all that is required but sometimes this cannot be tolerated. If the patient experiences relief when the lower chest is grasped and steadied by the doctor's hands, then strapping or firm bandaging should be applied.

Ice-bag often gives relief, but the method is that of a hypodermic injection of morphine, or a dose of tincture of opium, or other opiate such as Dover's powder or emulsion. So long as the air passages are dry morphine can be given without hesitation for the relief of pain. If morphine fails, as it may, I should not hesitate to follow the advice of Professor Wynn and introduce 400 to 500 c.c. of oxygen or air into the pleural cavity.

Insomnia is another dangerous symptom because of the resultant nervous exhaustion and it is most important that sleep should be secured in the early days of the illness before the condition is critical. Sleep must be obtained for excitable, nervous, and apprehensive patients. A cool quiet room and hydrotherapy tend to produce sleep but may not suffice. If pain is the cause of insomnia sleep will ensue when the pain is relieved. When in doubt rather than risk a restless and fatiguing night, an opiate should be administered. An ounce of whiskey or brandy, given as a hot drink with the opiate, has a definitely soothing effect, and may prove comforting to the patient. Paraldehyde in doses of 2 drachms with an equal amount of brandy pre-erupts in emulsion in peppermint water, is another satisfactory although unpleasant hypnotic. After the fifth day opium and its derivatives must be given cautiously, especially if there is undue secretion in the air passages. In the wild delirium sometimes also met, which may occur at the crisis there is of course no option. Morphine, alone or combined with hyoscyne, is the only remedy.

#### Cardiac Failure

From the first the management of the case is directed towards the prevention and treatment of cardiac failure. One factor in the production of cardiac failure is the toxæmia (always present though in varying degrees) which impairs the functioning power and the integrity of the myocardium, hits the central nervous system and interferes with vasomotor tone. A second important factor is anoxæmia. From various causes the blood flowing through the coronary arteries is deficient in oxygen. A third element is the stress on the right ventricle resulting from the pathological changes in the lung. Distension of the abdomen, with interference of the movements of the diaphragm is a further factor which sometimes adds to the difficulties of the right heart.

From the onset, management of the patient is directed towards preserving the functional integrity and efficiency of the myocardium. Vasomotor tone is maintained by hydrotherapy. The depth of the respirations is increased by cool fresh air and the relief of pain. Physical effort on the part of the patient must be reduced to a minimum. Toxæmia must be met when possible by specific treatment, by careful attention to the bowels, to the intake of fluids, and to the action of the kidneys.

At the first indication of cyanosis the administration of oxygen should be instituted. It should be given continuously for an hour at a time, and the result noted. Oxygen is probably the best cardiac stimulant. The difficulty is to get oxygen into the blood, the usual methods are ineffectual and more often act as a placebo to the relatives than as an efficient oxygenator. The funnel method is futile unless the funnel is large and applied close to nose and mouth. More efficient is a No 10 catheter with three to four apertures inserted into one nasal orifice after de-ensuring the mucous membrane. The other nasal orifice should be blocked with cotton wool or compressed by the

nurse during each inspiration, nevertheless this method does not compare with the mask. Experience, however, is that patients will very readily tolerate anything applied over the nose and mouth, especially if they are partially delirious.

Barach (*Arch. Int. Med.*, 1926 vol xxxvii) has described an apparatus used by him with success—a glass nose-piece and rebreathing apparatus by which a 40 per cent oxygen mixture in the nasopharyngeal air is obtained. Still better results followed the use of an oxygen tent. In his opinion the value of oxygen is supportive and not curative. It tends to prolong life until such time as the immunity mechanism is able to accomplish recovery. The use of oxygen through alcohol is merely fooliness. There is considerable moisture in the air passages it is well to combine the administration of oxygen with hypodermic injections of atropine.

#### Digitalis

There is no agreed opinion as to the value or the effect of digitalis in pneumonic patients except in those in whom fibrillation existed before the onset or when it originates during the infection. It is obvious that if pneumonia is superimposed on fibrillation the fibrillation must be controlled by digitalis, and the control maintained, a daily total of 45 to 60 minims of the tincture or other adequate preparation must then be given from the first fibrillation occurring during the course of the illness must be treated in the same manner. If no member of the digitalis group has been exhibited before the onset of the fibrillation, then I should not hesitate to give an intravenous injection of strophanthin, but my experience is that this toxic form of fibrillation—especially in the influenza type of pneumonia—does not respond satisfactorily to digitalis and its allies.

In an interesting communication by Levy (*Arch. Int. Med.*, September, 1923) it was shown that the tendency to dilatation of the heart in pneumonia was demonstrably lessened by adequate doses of digitalis. He was dealing with hearts whose fundamental rhythm was normal. It has also been shown that digitalis has a favourable action on the efficiency of the heart irrespective of alteration in the rate. The contractility is increased.

I believe we are justified in looking upon the routine exhibition of digitalis as of value. To be efficient it should be given from the first in adequate doses—from 45 to 60 minims of the tincture in each twenty-four hours. In the short period covered by an acute pneumonia it is unlikely that any toxic effects will be produced with the above doses, nevertheless careful supervision is essential, and by the fifth or sixth day the dose may require modification.

#### The Administration of Alcohol

The general public still has implicit faith in alcohol as the cardiac stimulant and it is evident that there are some members of our profession who even now believe that alcohol in some peculiar way—in its specific action—increases the efficiency of the heart. In a recent textbook in the section dealing with pneumonia I find the following: "Alcohol is often useful it should not be given too early in the attack but where there are indications of incipient cardiac weakness 4 to 6 oz daily may be given, and this even to children. Four to six ounces of alcohol in twenty-four hours is no mean dose."

So far no scientific evidence has been advanced in favour of the view that alcohol in its specific action is a direct cardiac stimulant and I am convinced that the prognosis in any particular patient is rendered graver by repeated doses of alcohol administered to prevent or counteract cardiac failure. Like most other medical men of my age, I was trained to prescribe alcohol freely at the first indication of cardiac weakness and it was not for some years that as the result of clinical observation I began to question the value of this line of treatment.

In the years 1899 to 1901 while resident medical officer in a large urban infirmary, I made a careful and serious attempt to determine whether pneumonic patients did better with or without the administration of alcohol, and careful notes were kept of 150 cases. Forty-seven were treated without alcohol, 103 received alcohol when

the ordinarily accepted indications for its use rose. The patients in each section were of the same type, and they were drawn from the same districts of the city. On certain days of the week every case of pneumonia admitted passed into the first group. On the remaining days the pneumonias were drifted into the other group. In this way, if there was a variation in the severity of the prevailing infection, both groups were affected equally.

The results were remarkable. They left no doubt in my mind that alcohol, given to fortify and strengthen the heart, failed in its purpose, and instead of helping the patient to fight his infection materially diminished his chances of recovery.

In Section 1, treated without alcohol, of the 47 patients 14 died—a mortality of 29.5 per cent. In Section 2, of the 103 patients 47 died—a mortality of 45.5 per cent, a difference of 16 per cent. The average age in each group was 35 years.

I thought that this remarkable difference in mortality might be due to a relatively greater number of moribund patients being admitted into the second section, and in order to eliminate that factor I deleted all those who had died within twenty-four hours of admission. I found that 5 moribund cases were included in Section 1, and 16 in Section 2. The revised figures, after deducting those patients moribund on admission, are as follows:

Section 1—42 cases with 9 deaths—a mortality of 21.4 per cent. Average age 34 years.

Section 2—87 cases with 31 deaths—a mortality of 36.8 per cent. Average age 32.8 years—on the whole a younger group.

We find a difference of 15 per cent in the mortality remaining after the elimination of those moribund, the two sections having, for all practical purposes, the same average age.

I do not wish to stress unduly the actual figures. There were possibly some unrecognized factors responsible, in part, for the lowered mortality in Section 1, but in view of the fact that the only material difference in the treatment of the two groups was in the administration of the withholding of alcohol, I consider it reasonable to assume that this was at any rate the dominant factor.

Further experience has convinced me that alcohol is only of use to pneumonic patients under certain well defined conditions, and that it is not only futile, but detrimental, when administered in repeated doses to help a failing heart. It may be of service, either alone or in combination with other sedatives, in procuring rest and sleep during the acute stage of the disease. It may be comforting, given in a hot drink during the initial rigor, and no objection could be taken on therapeutic grounds if alcohol in some palatable form were ordered during convalescence. But to give alcohol in the belief that it is a cardiac tonic or stimulant is opposed to scientific teaching and clinical experience.

One most important action of alcohol in the blood stream, and an action generally overlooked, is its effect on the immunizing response of the body. Recovery, in pneumonia, depends on the production of antibodies, and alcohol has been proved to inhibit this vital activity on the part of the organism.

Professor Winn sums up this aspect of treatment tersely when he says: "No proof has yet been advanced that alcohol is of service in cardiac failure, and to give, under the guise of a stimulant, a depressing drug which, moreover, inhibits the immunizing process, to patients who are unable to neutralize its effect, cannot be sound treatment." With this I agree.

I have already mentioned the value of glucose taken by the mouth and there is an increasing volume of evidence in favour of administering it by the intravenous method. 250 ccm of a 10 per cent solution of glucose in normal saline is injected every eight hours, or at longer intervals if considered necessary. Glucose is a valuable heart food. The injections tend to fortify the heart and incidentally soothe and comfort the patient. Another method of administration—namely, though of questionable efficiency—is that of adding glucose to a saline enema.

A material drop in the blood pressure is of serious moment, and indicates failure in the cardio-vascular apparatus. In such circumstances pituitin, 1/2 to 1 ccm,

should be injected every four to six hours, and an ice bag applied to the abdomen.

Pügge (*Deut. Arch. f. Klin. Med.*, 1922, April 18th) has used intravenous injections of hypertonic saline in the critical periods. He states that 100 ccm of 25 per cent salt solution raises the blood pressure 15 to 35 mm of mercury, and that this rise is maintained for about six hours.

Caffeine is a direct cardiac stimulant, and also stimulates the vasomotor centres. It can be administered as strong coffee, as caffeine, or the citrate, and there are several preparations on the market for hypodermic injections. If the patient is restless, or has difficulty in sleeping, it is wise not to give coffee in the late afternoon or evening.

In strychnine we have another drug very widely employed and with a reputation beyond its merits. Hypodermic injections are commonly given in the belief that the strychnine is a direct cardiac stimulant. There is, however, no evidence that it has any specific action on the heart. It acts rather on the respiratory and vasomotor centres, and in this way may prove of service in the latter days of the disease.

Intensection is occasionally of value. It will temporarily relieve the heart in the first few days, when the right ventricle is struggling to adapt itself to the mechanical difficulties imposed upon it by the rapid consolidation of lung tissue. Later on, engorged jugulars, an increase of the cardiac dullness to the right, and marked cyanosis would justify blood letting. The relief is only temporary, and is of value in so far as it enables energetic measures to be instituted for the salvage of the cardio-vascular mechanism.

Probably ammonium carbonate is more commonly prescribed in pneumonia than any other drug. Its action is that of a crumulative, a respiratory stimulant, and an expectorant, its chief value is when there is free bronchitic secretion, embarrassed breathing, and increasing cyanosis. It is of questionable value in the first few days unless there is an associated bronchitis. Fairly large doses should be administered, such as 10 grains every two hours, followed by a hot drink and a definite attempt on the part of the patient to expectorate.

There are other lines of treatment which have had a vogue, and other drugs from which benefit is said to accrue. To mention a few: potassium iodide and creosote, preparations of quinine, calcium chloride, bismuth chloride, camphor, and diathermy. In practice the wise man uses few drugs and understands their action and their dosage.

In the discussion which follows I would suggest that attention be directed more particularly to the larger issues. Let us pool our experiences in regard to the efficiency and practicability of specific treatment, serums and vaccines, the value of alcohol, the indications for morphine and digitalis, and the best methods of administering oxygen. Along such lines a discussion must prove of exceptional value.

## II—THE VACCINE TREATMENT OF ACUTE PNEUMONIA

BY

W. H. WINN, M.D., F.R.C.P.

Professor of Medicine in the University of Birmingham

APPARENTLY the chief obstacle to the general employment of vaccines in acute infections, such as pneumonia, is the fear of obtaining a reaction—a phase of lowered immunity—which might harm the patient. It is not sufficiently understood that a reaction only occurs in a person who is sensitized, whose cells are allergic. This state of sensitization is due to the presence of specific antibodies. If these antibodies are absent there is no sensitization, and it is impossible for a reaction to occur. We see this clearly in tuberculosis. It is quite safe to inject a whole cubic centimetre of old tuberculin into an uninfected infant who has had no experience of the infection, whereas a tuberculous adult may react to the one hundred-thousandth of a cubic centimetre.

Specific antibodies are present in all stages of chronic infection, and therefore reactions are easily produced in chronic bronchitis, asthma, chronic arthritis, chronic septicaemias, unresolved pneumonia, and so on. In acute infectious they are only present after a certain interval has elapsed, as the process of their formation is comparatively slow. It is this interval after infection and before sensitization that affords us the opportunity of intervening safely with an injection of a fairly large amount of vaccine without fear of producing a reaction.

CHART 1.—Lobar pneumonia. Inoculated on first day

In pneumonia the curve of intoxication probably rises rapidly and then remains fairly steady corresponding roughly with the temperature chart. At first antibodies are absent, but about the fourth day they begin to be present, the rise of their curve is at first slow, then rapid, and about the end of the week the antibody curve overtakes the curve of intoxication and a crisis occurs. The problem is to produce an early rise in antibodies while the curve of intoxication is still ascending and crisis to overtake, and before the toxins are fixed in dangerous amount in the nerve and heart cells. There is an interval in which the patient is sensitized, and it is found as a matter of experience that if during that interval we inject an adequate amount of a suitable vaccine we can to a large extent control the infection. It is obvious that the earlier the injection the more successful the results should be.

The first action of the vaccine appears to be a non-specific one; it is not too rapid in the production of specific antibodies, which rise only after effect.

For acute lobar pneumonia I use a stock vaccine of pneumococci made from primary growths under twenty-four hours old. The vaccine contains several strains but it is more important that it should be an active vaccine from virulent organisms. For an adult at least 100 million should be injected for a child aged 12 half the dose and a child aged 3 or 4 a quarter. As at present true lobar pneumonia is comparatively infrequent and the majority of cases are severe broncho-pneumonias of mixed infection, I use a vaccine containing equal parts of pneumococci, streptococci and *D. bifidus* at 100 million of each.

In either case the important thing is to inject early. I would not treat pneumonia as a regardable as an acute emergency requiring prompt action as in cases of surgical emergencies such as a perforated ulcer. Our plan should be "strike early and strike hard." It is a great advantage of vaccine treatment that a successful vaccine can be at hand and injected at once. The object is to control the infection as soon as possible after its onset and so prevent dangerous intoxication. After the toxins are fixed in the

cells the issue is out of our hands. If injected within the first twenty-four hours after the initial rigor it is my experience that in the majority there is a fall of temperature combined with general improvement during the following twenty-four hours. The earlier the injection the more certain the result. If the first injection fails we can repeat the vaccine every twenty-four hours.

The charts show the results of injection on the first, second, and third days respectively. The first chart is that of a man, aged 40, who was injected three and a half hours after his rigor. He already had blood stained sputum,

CHART 2.—Lobar pneumonia. Inoculated on third day

pain in the side, grunting respiration, a temperature of 105°, and a respiration rate of 38. 100 million pneumococci were injected. The temperature steadily fell and reached normal in sixteen hours. For a few days he had consolidation of both lower lobes with a complete absence of symptoms.

The second is that of a man of 53 seen one evening. A rigor had occurred in the morning; his temperature was 103°, respirations 32, and pulse 136. There were early signs in his right lower lobe. He received an injection of 100 million; his temperature fell and in the morning was normal, with a pulse rate of 63 and respirations 20. He was out of bed in a week and at the end of a fortnight.

Again was seen the striking phenomenon of a man with a portion of his lung solid, and yet a complete absence of symptoms. The vaccine appears to hasten consolidation which is a protective reaction and it also quickens resolution.

The charts of patients injected during the second day show a similar result but a second injection is more often required. When injected on the third day the fall of temperature is usually

more gradual and more than one injection is required, when injected first on the fourth day again the fall is more gradual and crisis is less easily obtained.

The results in 100 consecutive patients were that 49 were injected during the first three days, of these only one died. This was a pregnant woman who had been a chronic asthmatic and was confined forty-eight hours after the onset of pneumonia. Of 51 injected after the third day 12 died. This shows the importance of treatment before dangerous intoxication has occurred.

Of patients injected during the first day 83 per cent had a normal temperature in ten to four hours and 103 per cent in forty-eight hours. Of those injected on the second day 57 per cent had a normal temperature in twenty-four hours, 93 per cent in forty-eight hours, and 100 per cent in seventy-two hours, whereas of those injected for the first time on the third day only 20 per cent had a normal temperature in twenty-four hours, 60 per cent in forty-eight hours, and 73 per cent in

CHART 3.—Lobar pneumonia. Inoculated on second day

seventy-two hours. I think those figures again show the importance of early treatment.

I have some charts of influenza pneumonia injected on various days which show the same influence of a vaccine in shortening the duration of the disease.

Apparently Professor Hry holds that if vaccines prove to be successful in pneumonia it will be the first instance of the success of vaccines in acute infections. On the contrary I hold that acute infections offer the most brilliant examples of successful vaccine therapy, its use in pneumonia is merely an application of a general principle—that any acute bacterial infection for which an appropriate vaccine can be prepared, and which can be treated early, may be aborted by timely injection.

In vaccine therapy, therefore, I consider that we have a weapon which can be applied promptly and effectively, and which, if used on a large scale, would help to reduce the very high mortality from pneumonia.

#### DISCUSSION

Dr H. MORLEY FLETCHER (London) endorsed Dr Hry's condemnation of the gumgee jacket. He thought that morphine could safely be given, if necessary, during the first three, or perhaps four days, but afterwards should be withheld unless there was some urgent indication for its use. One of the dangers attending the use of morphine in the later days of the illness was meteorism; he had seen this occur with fatal results on several occasions shortly after the administration of the drug; the sudden abdominal distension increased respiratory embarrassment. The deleterious action of alcohol on the cardiac muscle was recognized and also the fact that it might act as a cell poison, but it should not be withheld indiscriminately in pneumonia, which was an acute illness of short duration, there was no direct evidence that a moderate dose of alcohol given for a few days could affect the heart muscle to any serious extent. It promoted sleep and also might be of considerable use in the crisis in cases exhibiting signs of collapse which so often accompanied the fall of temperature. He did not consider alcohol in any form necessary for young adults in the absence of special indications. The treatment of pneumonia by diathermy, recently advocated by Eaton Stewart, should be thoroughly investigated. Sodium nucleinate had been recommended by Gardner-Medwin in cases of pneumonic patients exhibiting a leucopenia or low leucocyte count. It had been claimed that injections of this drug given on one or two successive days stimulated leucocytoesis and were followed in forty-eight hours by crisis. These results by Gardner-Medwin had not been confirmed by Dr Morley Fletcher's investigations of cases of lobar pneumonia or of other infective conditions. The clinical evidence of toxæmia was cyanosis but in some cases of pneumonia increasing pallor might take its place. Cyanosis and rapid breathing might be present before the signs of consolidation appeared. The best therapeutic measure for combating toxæmia was oxygen, but it was usually given too late in the course of the disease or as a last resource when all hope had been abandoned. He thought that oxygen was the most valuable agent available for the treatment of pneumonia, but it should be given early, systematically, efficiently, and in sufficient quantity. In the case of adults it should be administered more or less continuously as soon as the diagnosis was made. Oxygen lessened the toxæmia and so reduced the risk of cardiac collapse, it was also a cardiac stimulant and had a marked effect in calming delirium and promoting sleep. It had been suggested that the delirium of pneumonia was due to unoxidized toxic bodies in the circulation, and this might be some explanation of the calming effect of oxygen on delirious patients. In his opinion the intranasal tube was the most useful method for the administration of oxygen, as it was efficient and easy to manage. It was first employed in Edinburgh in 1910 by Thomson and Dunlop. It was a method which could be used for infants with great facility. There had been much discussion as to the value of digitalis in acute febrile conditions, especially lobar pneumonia. The high pulse rate in pneumonia was not necessarily an indication of cardiac failure, but was due chiefly to the action of toxins on the cardiac centre. Digitalis did not lower the pulse rate in these

circumstances. Later, when the heart muscle began to fail, digitalis might be of great value, and there was no evidence that its action then was different from that produced in non-febrile failure of heart muscle. Cardiac failure in pneumonia might be recognized by increasing rapidity of pulse and the onset of irregularity due to auricular fibrillation. A further indication was the progressive fall of blood pressure. These signs of cardiac failure should be treated in the same way as when they occurred in non-febrile conditions—namely, by digitalis. Unfortunately they might manifest themselves suddenly, without warning, it was then too late to administer digitalis, as the time left was too short for its action to be exerted. In these circumstances strophanthin given intravenously and repeatedly was the best substitute. For this reason he held that it was advisable in a case of pneumonia in the late stage to give strophanthin preferably as the tincture. There was no satisfactory evidence against doing so, and the advantage to the patient at a later stage might be very great—in fact, it might determine the issue of the battle.

Professor R. J. S. McDOWALL (London) dealt with the methods for the relief of the heart from the physiological aspect. The heart had two loads: (1) it had to force out blood against diastolic pressure, (2) it had to pump out the blood which filled it at the end of diastole, in pneumonia the load at the end of diastole might be appreciably in excess of normal. Conditions which raised the carbon dioxide contents of the blood tended to raise the venous pressure, in health the heart responded by increased force and rate of the beat, but when the heart was poisoned there was the possibility that it might be filled with more blood than could be pumped out. Cardiac tonics, although assisting the heart, might also hamper it by constricting the blood vessels and so increasing the work the heart had to do. The most physiological method of relieving the heart was by bleeding, and as the high venous, and possibly a high pulmonary, pressure was partly responsible for the cardiac failure there was much to be said for bleeding before the actual stage of failure was reached. It had been objected that the effect on the arterial pressure was only temporary, but what happened was that the arteries became constricted to keep up the arterial pressure, the venous pressure fell in consequence, and the fall was prolonged. The fall was accompanied by a reduction in the viscosity of the blood, and these two factors must relieve the heart appreciably. There was also evidence that the blood had an increased bactericidal power after bleeding. Alcohol was a drug which reduced venous pressure, although it might have little or no action on the isolated heart there seemed to be no doubt that in the intact animal it did cause a fall in this pressure. Adrenaline might be tried in the treatment of the shallow respiration which was partly responsible for the faulty aeration of the blood. The shallowness was thought to be due to an exaggeration of the Hering-Breuer reflex, and he had recently found experimentally that adrenaline had a distinct action in abolishing this reflex.

Dr STANLEY DAVIDSON (Edinburgh) put in a strong plea for serum treatment, though he could not give any figures obtained in this country in support of his plea, as it had never received a serious trial, but the indirect evidence obtained by experiment and the direct evidence of the results obtained at the Rockefeller Institute were overwhelming. The clinician might obtain great help from a trained bacteriologist, films of sputum showing great numbers of pneumococci and positive blood cultures persisting after the onset of the disease were of bad prognostic significance.

Sir JAMES BARR said that it would often be much better to consider the treatment of the patient suffering from pneumonia rather than the treatment of the disease. The mortality would probably always be rather high owing to failure of the defensive mechanism. Prevention was better than cure, and if half the money spent on the prevention of tuberculosis were devoted to the simpler problem of the prophylaxis of pneumonia there would be a different result. The drawback to vaccine prophylaxis

was its short duration, but even a short immunity was a decided gain. If the severe chill in the early stage was recognized and dealt with promptly and efficiently an attack of pneumonia might be warded off. An important point in treatment was to get as many free calcium ions into the blood as possible and to avoid decalescing agents.

Dr A. F. HERRAT (Edinburgh) expressed his strong belief in the value of alcohol in the treatment of pneumonia. He said he would feel greatly handicapped in dealing with any case of pneumonia if he knew that alcohol must be withheld.

Dr F. M. GARDNER MEDWIN (St Asaph) described some of his results with sodium nucleate. He had found that all types of lobar pneumonia responded to a single dose of sodium nucleate, the pneumonic process being terminated in forty-eight hours after its administration. This result was independent of the period of the disease at which the drug was given. The first cases Dr Willmore and he had treated were cases of heliotrope cyanosis with high fever and delirium, such patients ordinarily all died, but with sodium nucleate they recovered. Professor HAY had stated that probably 10 to 15 per cent. of all pneumonia patients were doomed from the first to die. Dr Gardner-Medwin believed that an intramuscular injection of sodium nucleate with plenty of soda glucose lemonade, would save 90 per cent. of these "doomed" cases.

## THE INFLUENCE OF INTERNAL SECRETIONS ON SEX CHARACTERS

BY

F. A. E. CREW, M.D., D.Sc., Ph.D., F.R.S.F.D.,  
Animal Breeding Research Department, University of  
Edinburgh

THE sexes are to be distinguished by differences in details of structure and of function, and maleness and femaleness can be defined. For purposes of discussion it is convenient to classify the sex dimorphic characters as (1) primary genotypic, (2) secondary genotypic (including the primary gonadic), and (3) secondary gonadic. In the establishment and maintenance of this sex dimorphism the component members of the endocrine system, it has long been recognized, play a most important part. That this is so is illustrated in the following aphorisms, which in their sequence show the historical development of the modern point of view: "Propter solum uterum mulier est, quod est"; "Propter solum ovarium mulier est, quod est"; "Propter secretionem internas totas mulier est, quod est."

There is no difficulty in demonstrating that the physiological activity of the gonads is a condition of the normal development and maintenance of such of the sex dimorphic characters as are secondary gonadic, since by definition these are such as are dependent upon the gonad. The criterion of a secondary gonadic character is that it reacts to the physiological activity of the gonad in a particularly definite way. It is established that the gonadic influence punctuates the growth of the long bones, thereby affecting the general proportions of the body, that it influences the development and the functioning of the central nervous system and affects the processes of general metabolism. But in addition, and especially, the physiological activity of the gonads exerts a strong and definite influence on certain structures and functions which constitute the commonly and readily recognized sex dimorphic characters.

The intimate and significant relation between gonad and secondary gonadic characters is revealed by the results of (1) gonadectomy, (2) gonad implantation, and (3) administration of prepared products of the gonads.

### Gonadectomy

Castration of the newborn male rat is followed by a non-development of the genitalia, but has no effect upon general development. Since there is a sex dimorphic difference in growth rate, and since orchidectomy does not affect general development, it would seem that growth rate is dependent upon sexuality—that is to say, is a

secondary genotypic character, but that it is not a secondary gonadic character. However, it is more probable that the male type growth rate of the castrated rat is due to the after action of the gonadic hormone. In the case of the female the ovary does not function during the antepubertal period. This can be demonstrated by injecting ovarian extract or by implanting adult ovary into the immature female, when rapid growth and differentiation of the genitalia ensue, though only in cases in which these have already attained a certain stage of growth.

The effect of castration varies according to the age at which the operation is performed. Following prepubertal orchidectomy (later than in the case of the newborn) the genitalia do not develop normally—*peris vasa deferentia*, seminal vesicles, and prostate remain incompletely developed and of small size, though the corpus cavernosum attains its full development. In the human the beard does not grow until in old age the castrate develops one similar to that of the aged female. The hair in the region pubis comes to a horizontal hair line whilst the chest, axillae and the extremities remain hairless. The localization of subcutaneous fat is characteristic, much accumulating in the gluteal region, under the breast, in the trochanters, on the mons veneris and on the lateral aspects of the upper eyelids. The zone of proliferation of the epiphyses of the extremities persists even to the age of 35, so that the castrate attains a relatively greater height with disproportion of the body. The pelvis remains infantile, as does the larynx. The pituitary commonly undergoes enlargement so that the sella turcica is increased in dimensions. Erection and cohabitation remain possible for a considerable time in some cases. The general intelligence is not obviously affected, but general apathy is characteristic.

Post pubertal orchidectomy is followed by a non-development or a disappearance of the beard and a change in the regional distribution of the body hair, and a localized disposition of subcutaneous fat. The larynx becomes small and the voice high pitched. Sexual libido may persist for some time but ultimately disappears.

Ovariectomy in the human is performed late in life and the sequelae are therefore not well marked. Atrophy of the genitalia takes place especially of the vagina and the uterus. A marked accumulation of fat and an increase in body weight occur. Generally there is a decrease in the size of the breasts and in sexual libido. In some cases ill-defined premenstrual disturbances follow.

The evidence derived from the results of gonadectomy points to the conclusion that the development and maintenance of many morphological, physiological, and psychological characters are dependent upon the integrity and functional activity of the gonads. The gonads affect not only the component of the sex sex sexual apparatus but also such sex dimorphic characters as the regional distribution of the hair and the pitch of the voice. Metabolism is significantly reduced—that of fats particularly, that of carbohydrates less so, and that of proteins not at all. Following gonadectomy the next interrelationship of the members of the endocrine chain is disturbed and certain of the effects of gonadectomy may be due secondary to the indirect effects of this operation upon one other member or members of the endocrine system. It is seen that the effects of gonadectomy upon the sex-dimorphic characters vary according to the time at which the operation is performed in relation to the time of attainment of sexual maturity, prepubertal gonadectomy resulting in non-development of the genitalia and secondary gonadic characters whilst the effect of post-pubertal gonadectomy is in inverse ratio to the age of the individual at the time of operation.

There is no satisfactory evidence which supports the conception that gonadectomy not only leads to the disappearance or atrophy of homologous sex characters, but also to the appearance of the heterologous. The apparent swing of the characterization of the castrated male in the female direction is to be explained more simply on the assumption that there is an agonadic full grown form that the female sex characterization is nearer to this than the male, and that after gonadectomy there is a tendency on the part of individuals of either sex to swing towards the agonadic type.

The opening paper of a discussion in the Section of Physiology and Biochemistry at the Annual Meeting of the British Medical Association at Edinburgh.

*Gonal Implantation*

It is recognized that removal of the gonads is followed by a definite train of events, and it is reasonable to assume that the phenomena which follow gonadectomy are caused thereby. If this is so, then it may be assumed that the successful and timely implantation of appropriate gonadic tissue should result in the restoration of normal sexuality in the case of the agonadic individual, and implantation generally should be followed by phenomena which can be regarded as the effects of this procedure.

There is no difficulty in demonstrating that complete maleness and femaleness cannot be assumed and cannot be maintained in the absence of normally functioning pituitary, thyroid, adrenal, and so forth, but these endocrine glands stand in a different relationship to sexuality from that which the gonad occupies. Extirpation or disease of any of these in the mammal leads to the establishment of a distinct pathological condition, which can only be repaired by the restoration to the general economy of the disfunctioning or absent tissue. Gonadectomy, on the other hand, does not result in a diseased state; the individual becomes altered functionally and structurally, but the change is not so far removed from normality as to constitute disease. The gonads are especially concerned in the development and maintenance of sexuality, and it can be stated that the secondary gonadic characters, which are the most prominent of the sex-dimorphic characters, develop only when in an otherwise healthy body the gonids are functionally normal and active.

It is abundantly established that an animal which is castrated at an early age, and into which at the time of this operation its own testes or those from another animal from the same or from a nearly related species are successfully implanted, will develop normally in respect of the somatic functional and structural sex characters. The prostate, seminal vesicles, and penis in such animals develop so as to remain unexceptional. Partial or almost complete restoration of maleness is possible even in older animals castrated in early life, and the degree of restitution varies with the age of the individual at the time of castration and at the time of implantation, and with the length of the interval between the operations.

It is equally possible to restore femaleness in an individual previously ovariectomized by implanting ovarian tissue, and to prevent the sequelae of ovariectomy by implanting the individual's own ovary or that of a similar or nearly similar biological form at or about the time of ovariectomy. In such cases the uterus does not atrophy or it increases in size again, and in the human the menses return.

It is established that it is possible to feminize a male by castration and subsequent implantation of ovarian tissue. The latent homologous sex characters—for example, the mammary gland—are stimulated into activity, whereas the heterologous—for example, the penis, prostate, seminal vesicles—remain underdeveloped, or become diminished in size and complexity.

It is established that it is possible to masculinize a female by ovariectomy and subsequent implantation of testis. The uterus and mammae remain undeveloped or shrink, whereas the clitoris increases in size to such an extent that it resembles the male copulatory organ. It seems fairly clear, therefore, that ovarian and testicular hormones are sex-specific, acting only upon those structures with which each is normally associated. It may be, however, that for genetic reasons female tissues—that is, such as are genetically female—respond preferentially to the hormone of the ovary, whereas genetically male tissues respond preferentially to that of the testis. It is established also that the sex-hormones are not specific for each biological form of animal.

It is established that it is eminently possible to produce an artificial hermaphrodite by combining in one and the same body both kinds of gonadic tissues. A male with a normally functioning sex-equipment can following successful ovarian implantation, come to possess well developed mammae, and a female with a perfectly functioning reproductive system can harbor a testis graft which can proceed to spermatogenesis. Similarly, hermaphrodites can be produced through implantation of testis and ovary into an agonadic individual.

It has been recorded that such experimentation is followed by the development of bisexuality in respect of the psychical characters, but this has not yet been fully established.

In the case of the human, gonad implantation has been performed to "jockey" the individual's own gonads into a greater and more efficient activity, or to repair the agonadic condition. Many such operations have been attended with success, while others have not. Failure is probably due to imperfect technique, and to lack of a precise knowledge concerning the conditions within the body which are pre-requisite to successful implantation. Heterotransplants have not been very successful, and it is probable that in these cases failure is due to anathropic immunity, the host being unable to provide the implant with appropriate nutritional conditions. It is established, however, that testicular grafts from certain anthropoids can survive in the human body for many months, possibly even for years, and that the implants can exhibit a normal hormonal activity.

Such experimentation as this confirms the view that in the mammal one and the same somatic structure reacts differentially to ovarian and to testicular hormones. This may be due to the fact that the hormones are different while the soma of the two sexes is the same, that the hormone of the ovary is the same as that of testis while the soma of the male is different from that of the female or that both hormone and soma are different in the two sexes. It is probable that the last view is the correct one.

*Injection of Gonadic Tissue and Extracts*

The results of injection have been conflicting. Definite effects upon the circulation, metabolism, nervous system, and on the sex-dimorphic characters have been recorded, but in the main they have been effects which can be obtained by injection of extracts of animal tissues of all kinds, being characteristic of the action of proteins generally and not of gonadic tissue in particular. The effect of the extract must vary with the method of preparation and with the technique of administration. Moreover, it is not easy to reproduce the relation of gonad and soma by injecting gonadic material, particularly if such an organ exhibits a rhythm in its functioning, and if a quantitative action is involved. Though the evidence derived from injection methods is confusing, it can be said that this is due to imperfections in the methods of preparation and administration, and that there is nothing in this evidence which contradicts the point of view that the gonads, in their physiological functioning direct the differentiation, and ensure the maintenance, of many of the sex-dimorphic characters.

The part played in sex-differentiation by the gonads and other endocrine glands is well illustrated in cases of spontaneously occurring or experimentally produced abnormality of the reproductive system. For example, the individual with abdominal testes is infecund but not impotent, and the penis, prostate, seminal vesicles, and all the secondary gonadic characters develop normally. In its behaviour the male exhibiting cryptorchidism is hypersexed. Similar results follow double vasectomy and vasectomy and castration of the testes. In the case of the ovary also it has been established that the gonad exerts its action upon the soma even after the gametogenetic function is in abeyance or destroyed.

The action of the gonad is demonstrated in cases of intersexuality. In the human there are clinical records of cases in which a periodic change in the psycho-sexual characters was to be noted both in males and females. Several hypotheses have been advanced to account for this. According to one, the soma is perfectly ambivalent, but there are two forms of that particular gonadic tissue which is responsible for the elaboration of the specific sex-hormones. There is a physical basis for the female sex-hormone and another for the male. An individual may find himself or herself equipped with both kinds in the gonads or even with the kind appropriate to the other sex. Normally only the more potent of the two sex-hormones exerts its action, but physiological disturbances may upset the balance, and the other kind of sex-hormone will then exert its effects, and so with such characters as are capable

of responding to this fresh stimulus transformation in characterization can become evident. It is to be expected that the psychic characters, being more labile, will indicate this change more quickly and more thoroughly than will the morphological characters, which lose their plasticity much earlier.

Another hypothesis suggests that the gonad itself can be intersexual for genetic reasons, and that under the conditions the normal hormone elaborated by the normal gonad is not sufficiently potent to guide the differentiation of the sex somatic characters into a state of maleness or of femaleness. For genetic reasons also the gonad itself may be intersexual and it has been suggested that if this were the case the cure for homosexuality might well be implantation or injection of gonadic material. Such treatment has been practised. For example, the testes of a homo sexual man have been removed and those of a normal individual implanted with it has been claimed remarkable success. Other cases have not been successful. Such evidence as exists, however, permits one to assume with reason that many cases of homosexuality are due to some endocrine disturbance, though not necessarily a disturbance of an intersexual kind. In other cases it is by no means impossible that external agencies are responsible for the homosexual condition.

Medical literature includes many records of individuals in whom about the time of puberty a change of sexual characterization occurred. Commonly the case refers to an individual who, in early life, was with reason regarded as a female yet who later developed many of the typical male characters. Many such cases have been shown to be instances of masculinization of a female by a hypernephroma. Similar adrenal neoplasms in the male have led to precocious sexual development and it is recorded to advanced feminization. It is of importance to note that in these cases the effect of adrenal dysfunctioning is only evidenced in the presence of the gonad. In other cases intersexuality has been found to be associated with the presence within the body of both ovarian and testicular tissues. This condition is in every way equivalent to that of a perinatal hermaphroditism produced in the guinea pig and other laboratory animals.

There is yet another type of intersexuality which apparently is due to a different cause. In these cases the gonads are testes, usually intra-abdominal, but sometimes lying within the inguinal canals or subcutaneously; the necessary sex apparatus consists of well developed derivatives of both Mullerian and Wolffian ducts; uterus, vagina, vasa deferentia, sexual vesicles and prostate being present, whilst the external genitalia range in their form from that of an unremarkable vulva and clitoris to that of a grossly abnormal male with hypospadias and cleft scrotum. In these cases in which the external genitalia are of the female type the individual is regarded as a female. In all cases, however, with development and growth there comes the assumption of typical male characters—growth rate, voice, and regional distribution of hair whilst the psychic characters in the case of the intersexual human are confused through treatment. Such are the cases of young "women" who become "men."

It may be that these are really females genetically in which ovarian tissue existed in the earlier stages of development, but in which this disappeared to give place to testicular. It may be that these are instances of hermaphroditism in which the ovarian tissue undergoes removal. But it seems more reasonable to regard them as genetic males in which the appearance of the physiological activity of the testes was for some genetic reason delayed, so that the growth of the rest of those structures which constitute the sex-equipment was pursued in the absence or the directing influence of the gonad. If there is a time variation in the differentiation of the component parts of the sex-equipment, one structure becoming capable of responding to the stimulus of the sex-hormone of the testes before another then the degree of abnormality of the sex-equipment consequent upon a retardation in the exhibition of the stimulus will be a reflection of the degree of retardation. The facts that there is a very wide range of abnormality in these cases, that they can be arranged in a series with an almost normal female at one end and an

almost normal male at the other, that in all cases testicular tissue alone is found, whereas in none is evidence of degenerate ovarian tissues present, and that in all cases the later exhibited sex dimorphic characters are entirely and completely male point to the conclusion that the cases are males in which the time of differentiation of the testes has been abnormal.

The part played by the sex hormones in the production of this kind of intersexuality is best illustrated by the case of the bovine freemartin—a genetic female (XX) co-twin to a normal male—the reproductive system of which becomes abnormal during the period of sexual differentiation as a result of the action of the sex-hormone of a male co-twin *in utero*. Twins may be monozygotic or identical, and those arising from one and the same egg are always of the same sex and very similar in their characters, or they may be dizygotic or fraternal resulting from the synchronous fertilization of two separate ova. In the latter case they may or may not be of the same sex, and do not resemble one another any more closely than do brothers and sisters born at different times. Twins in cattle may consist of two normal males, two normal females, one male and one female, each normal or one male and the other an individual with an abnormal reproductive system and known as a 'freemartin'. In all save one of 126 cases of twins in cattle thoroughly examined two corpora lutea were found. This shows that twins are almost invariably dizygotic in this animal since two ova are concerned in female there is no such anastomosis.

The two fertilized ova pass into the bicornuate uterus and become attached to the uterine mucosa. If they have been discharged from the same ovary, the zygotes usually develop in one and the same uterine horn. As the zygotes increase in size the embryonic membranes of the two foetuses meet to adhere and in many cases to fuse. If such fusion occurs an anastomosis of their blood vessels can result so that a common vascular intercommunication may become established. It is to be noted that in the case of twinning involving one normal male and one normal female there is no such anastomosis.

Thus the situation arises in which the sex-hormone of each developing individual is at liberty to pass into the tissues of its co-twin. The sex hormone is the instrument which models the sex-organization alone. The internal secretions of the primary thyroid, adrenal and so forth, can also pass from each individual to the other but these are mainly concerned in the general and not in the special development of the individual, and will be able in both twins.

But if it so happens that the twins are bisexual (and a study of the sex ratio in cattle shows that by the law of probability three possible sex-combinations in twinning must occur in the proportion of  $1\sigma^2 : 2\sigma\eta : 1\eta^2$  and that the twin combination that includes a freemartin must be regarded as male-female) and if the fusion of the chorion occurs and further if a vascular intercommunication becomes established as it does in seven cases out of eight, the differentiation of both individuals will be directed by that sex hormone which is exhibited earlier, or which is more potent. The testis becomes differentiated at an earlier stage of development than the ovary and so the sex hormone of the male is liberated before that of the female. The female twin (that is genotypic female) will pursue her sex-differentiation under the direction of the male sex hormone of her co-twin and will therefore come to possess more or less completely the organization of the male. The assumption of the male characters in the case of the foetuses examined is imperfect: the external genitalia are of the female pattern, the internal organs of reproduction more or less completely male. The male sex-hormone is liberated before the embryonic gonads of the genotypic female have undergone differentiation into ovaries; such differentiation is prevented and so there is no question of a competitive action between male and female sex-hormones. The end-result will have a relation to the time of exhibition and to the efficiency of the male sex hormone. The variation in the size of the testes of the male co-twin and of the extent of vascular intercommunication seems to point to the conclusion that the amount of the hormone is not a significant factor in the production of a freemartin, but

that there is a minimum stimulus, and the reaction is of the "all-or-none" type. It is seen that the tissues of the genotypic male respond completely to the stimulus of the testicular sex-hormone, whereas those of the genotypic female fail to do so. Now it is known that genotypic male and female tissues are to be distinguished by differences in their chromosome content, and it is reasonable to assume that, because of these differences, they differ also in their physiological constitution. It is probable, therefore, that though both kinds may be capable of responding to one and the same sex-hormone stimulus, they will respond differentially. The male cootum develops testes because he is a genotypic male, and becomes a phenotypic male because he develops testes. His embryonic gonads become testes because their differentiation was pursued under the direction of the male-differentiating reactions elaborated by the interaction of the genes in the sex-determining gene-complex. The sex-hormone elaborated by the testes, passing into the body of the genotypic female, swings her sexual differentiation in the male direction, but the swing is not complete, because the sex-hormone of the testis is not equivalent physiologically to the male-differentiating substances elaborated by the sex-determining factors, and because her tissues are constitutionally different from those of the genotypic male.

It is seen that in the mammal the most distinctive sex-dimorphic characters are the secondary gonadic, and that for the development and maintenance of these the presence and action of functional gonadic tissue is necessary. The physiological action of gonadic tissues of the opposite sex causes the further development of incompletely differentiated structures to follow the direction appropriate to that sex, and, so far as is morphogenetically possible, renders the individual intersexual.

## AMOEBIIC DYSENTERY.

### I—INVESTIGATIONS INTO THE LIFE-HISTORY OF ENTAMOEBA HISTOLYTICA

BY

WARRINGTON YORKE, M.D.,

Professor of Parasitology, Liverpool School of Tropical Medicine and University of Liverpool,

AND

A. R. D. ADAMS, M.D.,

Lecturer in Protozoology, Liverpool School of Tropical Medicine

It is now generally agreed that the function of the cyst formation in *Entamoeba histolytica* infections is the propagation of the parasite from one host to another. This belief is based on sundry observations of a more or less satisfactory nature. There is much evidence indicating that in ordinary circumstances the active amoeboid stage of the parasite does not long survive after passage of the faeces. Dobell and O'Connor (1921) write that "In ordinary circumstances the free forms cannot live outside the body for more than a very short time, they die if swallowed." This view is also shared by Wenyon (1926), both as a result of personal observations and of his researches into the literature on the subject. Wenyon also states that "unless cysts are present the animals cannot be infected by feeding." In short, it was until quite recently believed that there are two possible ways of infecting animals—namely, as Dobell and O'Connor write, "by feeding them upon the cysts of the parasite, or by injecting active amoebae into the large intestine."

In further support of the view that the purpose of cyst formation is solely for the propagation of the parasite from one host to another are the investigations which have been made on excystation. This work has suggested that the cysts of *Entamoeba histolytica* will hatch only after they have been subjected to the action of the gastric and pancreatic juices, or to that of the pancreatic juice alone. Study of the literature indicates that this hypo-

thesis is probably mainly based on the observations of Ujihara (1914), of Penfold, Woodcock, and Dier (1916), of Chatton (1917), and of Cutler (1919). Ujihara records that cysts after incubation with gastric juice for twenty-four hours at 37° C. remained for the most part undigested, but that pancreatic juice was much more active. Penfold, Woodcock, and Dier write as follows: "As excreting agents we have tried pepsin in an acid medium, bile, and pancreatic extract, either alone, consecutively, or together, as appeared indicated, but the only success we have had has been with pancreatic extract used alone." Cutler states that "if a solution of 'liquor peptiens' is first allowed to act on the cysts for a short time, followed by a similar solution of 'liquor pancreatius,' a very large proportion of the treated cysts react." Chatton's experiments were of a different type, but permit of similar conclusions, he fed cats with *E. histolytica* cysts, and sacrificed the animals after periods varying from three and a half to seventeen hours, careful examination of the contents of different portions of the alimentary canal caused him to draw the conclusions that cysts pass through the stomach without alteration, except for digestion of the chromidial bars, and that excystation takes place in the small intestine.

It is remarkable that these workers have either overlooked, or ignored, the very interesting paper of Darling (1913). Chatton, it is true, refers to his work, but offers no comment upon it. Darling describes the gradual disappearance of cysts from moist chamber preparations of heavily infected faeces, and also the development of amoebulae within the cysts, and their emergence. This statement is so definite, and based apparently upon such careful observations, that it is curious it should have escaped comment from those who later worked on the same subject. Probably there are several reasons for this, most influential of which was the general preconception that the cysts must be swallowed before they can develop, another consideration was, doubtless, the possibility that Darling's preparations were—as so often happens in the tropics—contaminated with free-living amoebae. However this be, the fact remains that Darling's work seems to have been more or less ignored, and the view generally accepted that *E. histolytica* only excysts when it has been swallowed and subjected to the influence of the digestive juices. Dobell and O'Connor (1921), in their book on *The Intestinal Protozoa of Man*, after considering previous work on the subject conclude that "it is certain that the cysts never hatch in the colon where they are found, or outside the body."

In 1924, however, an important piece of work was published by Sellards and Theiler, which indicated that *E. histolytica* cysts would hatch when injected intracutaneously into kittens, and their work, which was very carefully controlled, has more recently been confirmed by Horie (1925). This observation is naturally of considerable interest and reopens the whole subject regarding the conditions necessary for excystation of *E. histolytica*, possibly it may have some bearing on relapse production in amoebic dysentery, as it has been suggested by Sellards and Theiler that relapses may, at times, be due to excystation of cysts which have persisted for some time in the colon.

With the object of throwing light on the matter, we have during the past two years conducted numerous experiments, details of some of which have already been published elsewhere (Yorke and Adams, 1926 and 1927). In the present communication we propose to summarize the main conclusions reached in these papers, and to refer to other and more recent observations which appear to us to bear on the life-history of *E. histolytica*.

The work commenced with the inoculation of a couple of tubes of Locke-egg-serum medium (Boeck, 1924, and Boeck and Diholm, 1925) with a small amount of human faeces containing numerous cysts of *E. histolytica*, and incubating at 37° C. On examining the tubes next day we were surprised to find large numbers of active amoebae, morphologically indistinguishable from *E. histolytica*. As no vegetative amoebae were observed in the stool at the time of inoculation, it appeared that those present had originated from the cysts. Many similar

A paper read in opening a discussion on amoebic dysentery in the Section of Tropical Diseases at the Annual Meeting of the British Medical Association, Edinburgh 1927.

experiments with the freshly passed stools of the same patient and also with those stored at laboratory temperature for three or four days, gave comparable results as did likewise experiments performed with the stools of other patients which contained cysts of *F. histolytica*. We were therefore led to the conclusion that, contrary to the general opinion, *F. histolytica* cysts are capable of hatching *in vitro* in the circumstances are suitable.

In order to study under the most favourable conditions this very interesting phenomenon we devised various methods for concentrating the cysts and separating them from most of the faecal material and bacteria. That giving the best results is as follows:

A mass of faeces is ground up with water in a small mortar and the emulsion shaken up with 500 or 1000 ccm. of water poured into a tall glass cylinder and allowed to stand for fifteen minutes to permit the coarser faecal material to settle. The supernatant fluid is withdrawn and either centrifuged or allowed to stand overnight in a cylinder; the deposit is then taken up thoroughly with a solution of cane sugar in water of a specific gravity of about 1.070 and centrifuged at high speed. This procedure results in separation of the vast majority of the cysts from the remaining faecal material; the faeces being precipitated and the cysts floating in the supernatant fluid which is withdrawn, diluted with about four times its volume of water and again centrifuged at high speed; by this means a small deposit is obtained consisting of great numbers of cysts in a relatively minute quantity of faecal material. The deposit is then washed several times with water to get rid of all traces of sugar and the majority of the remaining bacteria.

Washed concentrated suspensions of cysts prepared by this method were found to give remarkably satisfactory cultures of *F. histolytica* the relatively few bacteria which such suspensions contained as compared with the original faeces enabled the excysted amoebae to become well established before the growth of bacteria snuffed them and owing to the great number of parasites such cultures contained, and the relatively minute quantity of faecal debris, we were enabled to study the stages of development of the cysts and their excystation, under most favourable circumstances, both in the living state and in stained preparations.

Before discussing the changes leading up to excystation it would be well to point out that the cysts passed by different patients and even by the same patient at different times vary greatly in appearance, especially in respect of the number of nuclei they contain, and of their chromatoid bodies and glycogen. Thus, on one occasion the cysts may be practically all uninucleate with much glycogen and but few of them containing chromatoid bodies whereas on another occasion the vast majority may be quadrinucleate, with chromatoid bodies and but little glycogen. To cite an extreme case:

A chronic dysenteric patient A. P. passed on Mar. 14, 1925 a stool containing numerous *F. histolytica* cysts. On making a differential count of an iodine stained preparation it was found that the various types—as regards number of nuclei—were present in the following proportions: uninucleate 5 per cent, binucleate 7 per cent, quadrinucleate 22 per cent and those with indeterminate nuclei 6 per cent. In a stool passed three days later a differential count revealed the various types of cysts to be present in the following proportions: uninucleate 83 per cent, binucleate 6 per cent, quadrinucleate 6 per cent and those with indeterminate nuclei 5 per cent.

The fact that a patient may pass practically only uninucleate cysts on one occasion, and only quadrinucleate cysts on another occasion is very interesting and its correct explanation would seem to us to throw important light on the life history of *E. histolytica*. But before going further into this matter we propose to take into consideration the changes occurring in the cysts during cultivation *in vitro*.

When the washed concentrated suspensions of cysts referred to above were sown on Locke-egg serum (LES) medium, and incubated at 37° C. the cysts were found to develop rapidly; the uninucleate and binucleate cysts quickly being converted into quadrinucleate individuals, and after a few hours free amoebae began to make their appearance in the cultures. A single example will make this clear:

A differential count in iodine showed that a concentrated cyst suspension contained 57 per cent of uninucleates, 18 per cent of binucleates, 15 per cent of quadrinucleates and 10 per cent of individuals in which the nuclei were either indistinct or the cysts were shrunken or granular after incubation of this suspension

on LES medium at 37° C. for three and a half hours the differential count was as follows: uninucleate cysts 4 per cent, binucleate cysts 8 per cent, quadrinucleate cysts 41 per cent, cysts with indistinct nuclei or shrunken and granular 33 per cent, free amoebae 14 per cent. More prolonged incubation resulted in almost complete disappearance of the cysts and their replacement by free amoebae; many empty cyst envelopes were also to be seen.

After much close study of fresh and stained preparations of cultures of different ages we are able to give the following account of the developmental stages in the cysts which terminate in excystation.

The youngest cysts are uninucleate and loaded with glycogen as development proceeds chromatoid bodies make their appearance, the nuclei divide, and the glycogen decreases in amount. Later the cyst becomes quadrinucleate, chromatoid bodies are well developed but the glycogen is much less evident or entirely absent. When the cyst is completely mature and ready to excyst, the nuclei are agglomerated and the cytoplasm is homogeneous and without glycogen; the chromatoid bodies are greatly reduced or absent. We have failed to observe any evidence of autolysis in the development of the cysts but we have frequently seen chromatium particles apparently extruded from the nuclei immediately prior to, or during division.

The recently excysted *F. histolytica* contain four closely agglomerated nuclei and the cytoplasm is very finely alveolar. It moves in a characteristic slug-like manner with the nuclei almost invariably anterior, and drag behind a more or less motionless tail as bacteria are ingested the cytoplasm becomes more alveolar and digestive vacuoles quickly appear.

In cultures the majority of the excysted quadrinucleate amoebae divide either directly or indirectly, into four uninucleate individuals but in a certain proportion the cytoplasm fails to divide and individuals containing many nuclei are developed; these multinucleate forms frequently grow to very large dimensions. Here again we were unable to observe any indication of autolysis.

These observations show that contrary to general belief *F. histolytica* cysts readily develop and hatch under suitable conditions *in vitro*. So far as we have been able to ascertain moisture and a suitable temperature (preferably about 37° C.) are essential for development and excystation; the passage of the cysts through such solutions as liquor pepticus or liquor pancreaticus is unnecessary for excystation.

Shortly after the publication of our preliminary paper, in which these observations are set forth in detail, a communication appeared from Dobeil and Laird (1926) which confirmed this work in so far as they state that they were able to initiate cultures from the cysts of *E. histolytica* passed in faeces. They however add that 'Cysts just passed in stools do not hatch or develop further if placed immediately in culture media and incubated at 37° C., they merely die. They must first be allowed to cool, and then must be kept for a certain time.' The time required for maturation outside the body is stated to be approximately one or two days. This statement obviously raises very important epidemiological questions for it implies that the faeces of chronic dysenterics are not infective for one to two days after being voided. It is furthermore in conflict with our own impressions, for although we had not specially investigated this point when we published our previous papers yet we have among our protocols many records of the successful initiation of cultures from *F. histolytica* cysts passed only three or four hours.

In view of the practical importance of the point it appeared to us desirable to reinvestigate the subject and with this object in view a number of patients suffering from chronic amoebic dysentery were from time to time brought to the laboratory and asked to evacuate their bowels, so that the freshly passed stools could be sown immediately on warm Locke-egg serum medium. A differential count in iodine of the various cysts and vegetative amoebae (that is, as regards the number of nuclei contained) was made immediately on passage of the faeces and also after cultivation on LES medium for hours. In all observations of this kind it was found that the cysts developed in a perfectly normal manner, the

majority of the uni- and bi-nucleate individuals becoming rapidly converted into quadrinucleates. When, however, we come to the question of excystation the problem is distinctly more complicated. Differential counts revealed in numerous experiments a very varying degree of excystation on some occasions none of the cysts hatched, but on others a considerable proportion were found to have excysted, the proportion varied greatly, but in no instance did it exceed 58 per cent.

In existing round for an adequate explanation of this defective excystation several possibilities present themselves. In the first place, although it is clear that the great majority of the uni- and bi-nucleate cysts were alive, as they developed into quadrinucleate individuals, it is possible that many or all of the quadrinucleates present in the faeces at the time of passage were dead, and such an hypothesis would explain the relatively small hatch usually obtained. In the second place, it is conceivable that, even though all the cysts were alive at the time of the passage, only limited excystation took place in certain experiments, and in others none at all, because, as Dobell and Laidlaw state, maturation outside the body at low temperatures is an essential factor for excystment, or, in the third place, some unknown factor in the conditions of the experiments might have been more or less inimical to excystment.

In order to investigate these points, and more particularly as to whether some at least of the quadrinucleate cysts were dead at the time of passage, or whether cooling outside the body is essential for excystation, experiments of the following nature were undertaken.

A differential count of the cysts and vegetative entamoebae in the stools of a chronic dysenteric was made immediately after passage in the laboratory, and a portion of the stool was sown immediately on warm LES medium. From the remainder of the stool a concentrated washed suspension of cysts was rapidly prepared according to the second procedure described in our first paper (1926), care being taken to maintain the temperature at 37° C throughout the operation. During the preparation of the cyst suspension, which occupied approximately one hour, all the vegetative forms were destroyed. A differential count of the cysts in the concentrated suspension was then made, and a portion was sown immediately on warm LES medium. Finally differential counts in iodine were made of each of the above cultures after incubating at 37° C for various periods.

The results of these experiments showed that, whereas the degree of excystment resulting from cultures of the original faecal mass varied from 0 to 40 per cent, that resulting from similar cultures of the washed concentrated cyst-suspension prepared at 37° C varied from approximately 60 to 95 per cent. From this we are able to conclude: (1) That cooling outside the body is not essential either for the development of the cysts or for their excystation. (2) That usually the great majority of cysts are alive at the time of passage, this is clearly evident from the fact that cultures of washed concentrated cyst-suspensions usually resulted in a hatch of 80 to 90 per cent of the cysts. On certain occasions, however, the fact that hatches of only 60 or 70 per cent were obtained, even under the most favourable conditions, suggests that an appreciable proportion of the cysts—probably of the quadrinucleate type—were dead at the time the faeces were passed. (3) As the relatively poor hatch obtained from cultivation of freshly passed faecal material cannot therefore be explained either on the ground that cooling outside the body is necessary for excystation or on the ground that the majority of the cysts were dead when passed, it must be the result of something in the faecal material itself which, although not preventing development of the cysts, does inhibit their excystation.

But before proceeding to further evidence in support of this contention it appears desirable to return to another question raised by Dobell and Laidlaw. These authors claim that it is only the completely developed cysts which survive cooling outside the body, they write "When this (cooling to laboratory temperature) is done all immature cysts cease to develop and likewise ultimately die, but all fully formed cysts remain alive and unaltered for a considerable time." This again raises a point of considerable practical importance, for it implies that a stool such as the one referred to above, in which the uni- and bi-nucleate cysts constituted about 90 per cent of

the total present, is relatively only very slightly infected after it has been passed for a short period.

Numerous experiments have satisfied us that cooling the faeces, or the washed concentrated cyst-suspension, either to 0° C or to laboratory temperature, for periods varying from an hour to two or three days, does not cause the uni- and bi-nucleate cysts to die more quickly than the fully developed quadrinucleate individuals. In fact, the evidence shows that cooling the faeces to 0° to 5° C for one or two days has no appreciable effect on either the immature or mature cysts.

Returning to the question of the inhibitory effect of faecal material on excystation, experiments of the following nature were performed.

A washed concentrated suspension of cysts, prepared as previously described, was sown on LES medium, and also on the medium to which had been added, either at the time of sowing or two hours previously, a piece of faeces about the size of a pea. Differential counts were then made after incubation at 37° C for various periods. In other experiments an extract was made by rubbing up a little of the faeces with Locke serum in a mortar, and then precipitating as far as possible the faecal material by prolonged centrifuging at high speed; the supernatant fluid was used for covering the egg slopes and after warming to 37° C the cyst-suspension was sown. Here again differential counts were made after incubating at 37° C for various periods.

The results of these experiments showed that the presence of faeces, or of faecal extracts, in the culture tube, had a definitely inhibitory effect on excystation, although it did not prevent the development of the uni- and bi-nucleate stages into the quadrinucleate.

Hitherto we have had no absolutely satisfactory criterion which would enable us to decide whether *E. histolytica* cysts are alive or dead. The usually accepted method of determining their viability is their behaviour in dilute eosin solution. This test is based on the assumption that dead cysts stain immediately with weak solutions of eosin in water, whereas living cysts do not, but whether this assumption is wholly justifiable is a matter of very considerable doubt, it is highly probable that the cysts which stain are actually dead but whether all those which do not stain are alive is a much more doubtful matter. The method described above of sowing washed concentrated cyst-suspensions on LES, and observing the proportion of cysts which have hatched after incubation at 37° C for various periods, has proved a much more reliable test of viability, and has enabled us to investigate certain important questions such as the longevity of the cysts under various conditions *in vitro*, and their resistance to heat and to various drugs and chemicals.

The results of such experiments have shown that *E. histolytica* cysts commence to die fairly rapidly in faeces which have been kept at laboratory temperature (16° to 20° C) for three or four days, and that all are dead within about ten days, approximately the same result is obtained when the faeces are kept at 0° C in the ice chest. When freshly passed stools are placed immediately in the incubator at 37° C, the cysts are found to be practically all dead within a period of less than twenty-four hours; the precise period appears to vary with different stools, and in some instances but few cysts survive for longer than eight or ten hours. Washed suspensions of *E. histolytica* cysts in water live rather longer, more especially when stored at 0° C, but even under these conditions live cysts are not found after three weeks.

*E. histolytica* cysts survive a temperature of 45° C for thirty minutes, but are killed within five minutes by a temperature of 50° C. The cysts are remarkably resistant to emetine and to Yatrien and relatively so to hydrochloric acid and chlorine, the last named, in strength far in excess of that used in the bacteriological sterilization of water, having no effect on the cysts within a period of half an hour.

Returning now to the interesting observations of Sellards and Theiler—that littens can be infected by intrarectal injections of *E. histolytica* cysts—we have already mentioned that these authors have advanced the hypothesis that relapses may, on occasions, be due to hatching of cysts which have persisted in the colon for some time. This is obviously a question of great practical importance, and merits serious consideration. Hegner (1927) refers to this work in his recent book, and writes as follows:

Irreversible excystation may also take place in the large intestine of man. Sellards and Thieier have gone even further and suggest that cysts may hatch in the colon of the amoeba individual in which they are formed. Pelpel in amoeba may according to this view result from the hatching of resistant cysts held for long periods in the intestine. However the observation of Dobell and Laidlaw that cysts must be cooled below body temperature for several days before they will hatch indicates that cysts could not hatch until they had passed out of the body of the host in which they encysted.

But as we have already shown, in the experiments recorded above Dobell and Laidlaw are mistaken when they state that cysts must be cooled outside the body before they can excyst and develop further, so that no valid argument appears, up to the present, to have been advanced against Sellards and Thieier's hypothesis. Many of the facts brought to light in our investigations appear, however, to bear on the matter and to indicate that cysts do not hatch in the body of the host in which they are formed.

The first question which of necessity arises in considering the subject, is the length of time *F. histolytica* cysts live in the human body. There seems to be no reasonable ground for doubting that the cysts are formed from the precystic stage either on the surface of the ulcer or, more probably, in the lumen of the gut. The period occupied by the conversion of the precystic stage into the cystic stage is not known, but such evidence as there is suggests that it must be comparatively short. The small precystic amoebae can often be found in small numbers if looked for carefully, in freshly passed stools which at first sight contain nothing but cysts. On several occasions saline enemata given to chronic dysenterics, whose stools contained apparently only the cystic stage produced large numbers of the precystic forms, and again it is generally recognized that an apertient will cause in similar cases the appearance of precystic amoebae in the stools. After the effect of the enema or apertient has ceased the precystic forms are again replaced by cysts. When once the cyst is formed it quickly develops at 37°C. into the mature quadrinucleate individual. Numerous experiments have shown that *in vitro* the uni- and bi-nucleate cysts are converted into quadrinucleates within a period of three to four hours. This fact affords an entirely satisfactory explanation of the observation previously referred to—namely, that the cysts passed by different patients, and even by the same patient at different times, vary greatly, on one occasion they are practically all uninucleate whereas on another occasion they are practically all quadrinucleate.

The stage in which a cyst is passed obviously depends on the length of its sojourn in the bowel, and as a general rule we have noted that in the case of a patient whose bowels are moved several times a day, the proportion of uninucleate cysts is materially higher than in cases where there is only one motion daily. There must be exception to this generalization as obviously the site of the lesion will exercise influence if the precystic amoebae are formed in ulcers situated in the caecum, the cysts other things being equal will naturally be longer in the bowel than if the site of their formation is in the lower 10 or 15 cm. of the rectum.

There is thus substantial reason for believing that the interval occupied by the development of the precystic stage into the mature quadrinucleate cyst is comparatively short, probably not exceeding six to eight hours. Furthermore experiments *in vitro* and *in vivo* show that under suitable conditions mature quadrinucleate cysts hatch within a few hours. It is unnecessary to mention again the *in vitro* experiments which we have already discussed fully but brief reference might here be made to certain hitherto unpublished *in vivo* experiments. It was found that when washed concentrated cyst-suspensions were injected intraperitoneally into mice, or subcutaneously into guinea-pigs, the cysts hatched within a period of three or four hours, and in a certain proportion of cases the infection developed, with the production of general peritonitis or large subcutaneous abscesses in which vegetative amoebae were to be found in considerable numbers. The observations are in agreement with those of Chaiton who found free quadrinucleate amoebae in the intestine of a kitten three and a half hours after feeding it with human faeces containing *F. histolytica* cysts. We can therefore conclude that under suitable conditions *E. histolytica* can

pass from the precystic form, through the various cystic stages to the excysted quadrinucleate amoeba within a period of twelve hours. If this happened in the bowel large numbers of cysts would be constantly hatching and wasted for the purpose for which they are intended, providing the patient did not have more than one or two motions daily. There is however very considerable evidence to show that this does not happen. In the first place notwithstanding the most careful search on innumerable occasions, we have never found in the stools any forms resembling the characteristic recently excysted entamoeba, with its four closely agglomerated nuclei and in the second place although the process of development proceeds apparently uninterrupted to the formation of the mature quadrinucleate cysts these do not hatch in the bowel, possibly partly owing to lack of sufficient moisture in the contents of the rectum but mainly because of the presence in the faeces of something which inhibits excystation.

Although the mature quadrinucleate cysts will not hatch in faeces, there is evidence that they will remain viable in the bowel for some time. How long, this is we do not know, but we have already referred to the fact that when infected faeces containing large numbers of quadrinucleate cysts, are kept in the incubator at 37°C. the cysts do not survive longer than from about eight to eighteen hours, the precise period varying with different stools. This does not of course, mean that they cannot survive for longer periods in the bowel as doubtless, changes inimical to the cysts occur in faeces kept outside the body at 37°C., but these observations together with the facts that in the stools of every patient we have examined a certain number of cysts appeared to be dead when passed, and that the number of these is greater in hard constipated stools suggest that the period for which the mature quadrinucleate cysts can live in the bowel is probably not more than a day or two at most.

Our investigations, therefore lead us to the belief that the development of *F. histolytica* from the precystic form to the fully mature quadrinucleate cyst proceeds steadily, and without interruption in the lumen of the bowel, and that the whole process occupies only a few hours, the mature quadrinucleate cysts do not hatch in the bowel, but can survive there for a period which is strictly limited, probably not more than a day or two at the outside. It is not easy to harmonize Sellards and Thieier's observation with these views but the following reflections appear to us to be relevant. Obviously there may be some essential difference between the human intestine and the rectum of a kitten and it is possible that the contents of a kitten's rectum may not have the inhibiting or inhibiting excystation as has that of the human intestine. Then again it must be remembered that the fluid is fatal for excystation and that this factor was applied in Sellards and Thieier's experiments in the form of the 3 cm. of saline in which they suspended the small quantity of faecal material injected. Such injections would probably lie, at first at any rate below the faecal mass in the kitten's bowel and in contact with the mucous membrane, and the cysts would not be so intimately intermingled with faecal material as is the case in the human intestine. It seems to us that it is quite probable that in such circumstances the conditions might not be sufficiently unfavourable to prevent entirely excystation of the injected cysts and that those which did excyst might succeed in penetrating Lieberkuhn's crypts and in invading the bowel wall of a susceptible animal like the kitten.

Notwithstanding therefore the interesting observations of Sellards and Thieier we adhere to the belief that the sole purpose of cyst formation in *F. histolytica* infections is the propagation of the parasite from one host to the next, and that Nature has devised a method of safeguarding this and of preventing the waste which would result if hatching of the cysts occurred in the intestine in which they are formed.

## II—RECENT ADVANCES IN THE TREATMENT OF AMOEBIC DYSENTERY

TOGETHER WITH AN ACCOUNT OF THE SIGMOIDOSCOPIC APPEARANCES OBSERVED IN DIFFERENT STAGES OF THE DISEASE

BY

PHILIP MANSON BAHR, D.S.O., M.D., F.R.C.P.,  
Physician to the Hospital for Tropical Diseases London, and to  
the Seamen's Hospital, Royal Albert Docks,

AND

E. G. SAYERS, M.B., CH.B.N.Z., D.F.M. AND H.,  
Late House Physician to the Hospital for Tropical Diseases,  
London

Cases of amoebic dysentery are not only difficult to cure, but they are also exceedingly common, and it is obvious that any step forward in treatment should be eagerly looked for and as readily tested.

The first really specific treatment of amoebic dysentery was with ipecacuanha. There is no question that in many cases it was efficacious, but it was soon superseded by emetine, which was introduced by Sir Leonard Rogers in 1911, who then prescribed ipecacuanha nowadays.

The introduction of emetine was a definite step forward, and it still seems to us to be the treatment of election in the early stages of acute amoebic dysentery and for amoebic hepatitis. However, even with careful treatment a certain percentage of cases relapse, and subsequent treatment with a further course of the same drug is often of no avail, in other words, the entamoebae in these cases have become emetine-resistant. Our experiences with emetine as a means of eradicating the intestinal infection have been distinctly disappointing, and the results of observations on 87 of the cases under our care in the Hospital for Tropical Diseases were published by Renne in 1922. Chronic cases, too, often do not respond at all well to emetine injections, and we have seen patients treated repeatedly with doses of 80 grains, or more, of emetine over a prolonged period without permanent benefit.

### *Emetine-Bismuth-Iodide*

Emetine-bismuth-iodide, which is given by the mouth, was then adopted in place of injections of emetine, and, undoubtedly, many cases which failed to respond to emetine were cured by this drug.

The following cases illustrate the remarkable curative effect of emetine-bismuth-iodide uncombined with any other form of treatment.

A marine who contracted amoebic dysentery in China in 1912 was seen in 1924 after repeated relapses, which during twelve years had been treated with emetine. There was extreme wasting, the weight was only 8 st 7 lb, the general condition was poor and the patient was passing about ten stools daily swarming

with active amoebae. Sigmoidoscopic examination showed numerous ulcers. After 36 grains of emetine bismuth-iodide he put on 7 lb in weight in ten days. He has remained free from symptoms since, and returned to work.

Another patient contracted amoebic dysentery in Trinidad in 1914; this was followed by frequent relapses till his admission to hospital in 1922. He was treated with many courses of emetine injected without avail. Great emaciation was present, and he lost 3 st in weight, while passing nine to twelve stools a day containing free entamoebae. A preliminary course of 10 grains of emetine bismuth-iodide, the more acute symptoms, but he continued to pass free entamoebae. He then had two full courses of emetine bismuth-iodide, one of 30 grains and another, two weeks later, of 16 grains. The stools had been free from entamoebae ever since the patient improved remarkably in general condition and had put on a stone in weight. For the last three years he had been back at his work in Ecuador, remaining free from symptoms.

The total number in this series treated with emetine-bismuth-iodide alone was 40 cases. Out of these there were 5 in which full courses of this salt and of emetine periodide had no permanent effect.

The more acute the symptoms, the more striking and permanent were the effects of treatment with emetine-bismuth-iodide.

Emetine periodide proved less satisfactory, for out of 12 cases treated with it, 5 had to be subsequently treated with emetine-bismuth-iodide in order to be completely cured.

Three of our patients treated with emetine-bismuth-iodide relapsed after as many as nine courses of treatment, demonstrating the well known fact that entamoebae become resistant also to this drug. There is no doubt that its introduction has considerably raised the percentage of cases of chronic amoebic dysentery permanently cured, but there still remains a fairly large residue who, in spite of all known treatments, live with the certainty that sooner or later they will relapse to their former condition, passing numerous stools with blood and mucus. Such patients usually become neurasthenic.

Not even the most enthusiastic advocate of emetine or emetine-bismuth-iodide would claim that such treatment is ideal from the point of view of the patient. The administration of emetine means a rather painful injection, and emetine-bismuth-iodide is notoriously likely to result in distressing vomiting. The well known toxic effects of emetine are also a much graver objection to its use, resulting, as a general rule, in an appreciable fall of blood pressure—about 20 mm of mercury. The circulatory system is particularly liable to be involved, and the very characteristic "emetine pulse," and cardiac irregularities of various types, are not infrequently seen. From the mental point of view emetine is sometimes a depressing drug, and a very painful neuritis and desquamation of the skin are well known sequels. We have found that such untoward symptoms are less likely to supervene if a more generous diet is allowed than the milk diet originally suggested. Still, in treating a series of cases, some will always be met with in which the full course of treatment cannot be tolerated, especially among women and children. A less toxic and more efficient drug had clearly become very desirable in the treatment of amoebiasis.

### *Yatren*

In 1921 P. Muhlens and W. Menk first introduced a new drug called Yatren 105. It is an iodine-oxyquinoline-sulphonate compound, and may be given orally, rectally, intramuscularly, or even intravenously. We have experience only of the first two methods, but have now used them on a large series of cases.

By the mouth the usual dose given by most workers has been 15 grains three daily, but we found that such a dosage caused diarrhoea, and were content with a smaller dose—4 to 8 grains three daily. It may be given in pill form or in cachets.

By the rectum yatren is given as an enema, the quantity used being 200 c.c. of a 2½ per cent solution. The rectum is first cleared out by a preliminary enema of 2 per cent sodium carbonate, 1 pint, and then the yatren solution is run in slowly and retained as long as possible. Most of the patients can retain it about six to ten hours, and after a little experience many of them can hold it for a much

longer period. Proof of absorption consists in testing the urine with iron perchloride, the reaction giving rise to a greenish colour.

The course of treatment adopted on the continent consists in giving it for ten days by the mouth combined with ten daily injections by the rectum. It is good practice to repeat the course after an interval of five to seven days. The diet should be light, and can include fish pudding and chicken a milk diet alone is quite unnecessary. Apart from the diarrhoea following large doses by the mouth we have observed no toxic symptoms attributable to ratren, and we have not been able to find any evidence of such in the literature. It certainly is a very safe drug, in spite of the large amount of iodine in the combination; symptoms of iodism are unknown. It is possible to give it to children, which is a great advantage as compared with emetine and emetine-bismuth iodide. Mild cases, such as cyst passers without symptoms, may be treated without confinement to bed but absolute rest should be part of the treatment of any more acute dysenteric condition.

The mode of action of ratren is a little uncertain, but it is claimed that it is a definite cell stimulant. According to Kofoid and Wagener it has in vitro no very powerful action on *Entamoeba histolytica*. On the other hand Vogel in a recent communication, has adduced clear evidence that ratren in a dilution of 1 in 100 is capable of exterminating all the entamoebae in artificial culture within a period of three hours and in a higher dilution (1 in 1,000), it prevents the multiplication of this organism from taking place after a period of twelve hours.

Ratren is certainly a safe non-toxic drug and much more pleasant from the point of view of the patient, who, as a general rule increases in weight during the treatment. We believe it to be a drug of the very greatest value and can fully confirm its efficacy in curing long-standing cases of amoebic dysentery which have proved resistant to emetine and emetine-bismuth iodide. This is illustrated by the following rather striking cases.

#### Cases Treated by Ratren Alone

Out of four cases treated by ratren alone which one of us reported in 1925 one relapsed subsequently, and was treated with emetine-bismuth iodide. Since then we can quote the following.

One patient had frequent relapses of dysentery dating from 1916 in Salonica. He was treated frequently with full courses of emetine and emetine-bismuth iodide. In hospital two weeks after a full course of emetine-bismuth iodide he developed amoebic hepatitis followed by a relapse of dysentery. In February 1925 ratren was given by the bowel for ten days and also ratren pills by the mouth 24 grains daily. The amoebae disappeared and the stools were reduced to one daily. He gained 5 lb in weight in ten days and in a month's time he had added another 16 lb. He returned to Nigeria and in February 1926 had had no relapse. He has remained in perfect health.

Another patient who contracted amoebic dysentery in 1922 in St Vincent had had 66 grains of emetine with frequent relapses and was invalided home. After admission to hospital he was treated with two full courses of emetine-bismuth iodide but he relapsed nine months later with amoebic hepatitis and dysentery. In November 1924 he received a full course of ratren by the bowel. He has remained in good health ever since and has returned to duty in the tropics.

A third patient had dysentery in Gallipoli in 1915. He was given numerous injections of emetine at the time and emetine-bismuth iodide in full doses in 1918 and 1919. In spite of this diarrhoea returned every two months with blood mucus and free entamoebae. He was given a course of ten ratren lavages in December 1925. He reported at the beginning of 1927 that he had been free from symptoms since the treatment.

The question naturally arises. Has ratren any value in the treatment of amoebic hepatitis? Beyond the case quoted above we have no personal experience of this but several cases presumably cured in this manner are recorded in the literature. Further observations on this point are necessary. The next question is whether ratren fails more often than emetine-bismuth iodide. To this it must be answered that, although its action appears to be curative when the lesions are situated in the lower portion of the

large intestine, there are patients who relapse owing to lesions in the caecum and transverse colon. To meet this contingency we have introduced what we believe to be the treatment of election for intractable cases of amoebic dysentery—that is, emetine-bismuth iodide given by the mouth and ratren administered by the rectum simultaneously.

#### Combined Treatment with Ratren and Emetine-bismuth Iodide

During 1926 the combined treatment has been given to 22 cases. 5 grains of emetine-bismuth iodide being given every night and ratren (200 ccm of 2 per cent solution) lavages in the morning. To our surprise this seemingly drastic treatment was well tolerated by the patient and the usual diarrhoeic effect of emetine-bismuth iodide when given alone was not observed. Vomiting was almost entirely absent.

From a clinical point of view these cases have been the most successful in a series of 153 proved cases of amoebic dysentery which we have quoted in this paper especially when it is remembered that most of them were war infections of long standing and especially intractable to treatment. The following illustrative cases are worth of record.

One patient had had uncontrolled dysentery for eleven years since his original attack at Gallipoli in 1915. He was given frequent courses of emetine and emetine-bismuth iodide without avail. In May 1926 when he was passing ven stools daily containing free *E. histolytica* he was given 27 grains of emetine-bismuth iodide combined with ten daily rectal lavages of ratren the treatment being controlled by sigmoidoscopic examination. He was in hospital for only sixteen days and has been perfectly fit ever since.

Another patient first contracted dysentery in India in August 1923. He had numerous courses of emetine and emetine-bismuth iodide in India. In September 1925 he was treated in a London hospital with emetine relapses were frequent. On admission to the Hospital for Tropical Diseases in February 1926 he was passing ten stools daily containing blood and mucus with free *E. histolytica*. He was treated with ratren alone by rectum and one month later he was then given emetine-bismuth iodide combined with ratren in two courses with an interval of one month. At the beginning of 1927 he was absolutely free from symptoms.

A third patient contracted dysentery in 1925 in Colombia. Numerous injections of emetine and courses of emetine-bismuth iodide were administered with only temporary relief. He was treated in various London hospitals without success. In October 1926 he was passing sixteen stools daily with numerous free *E. histolytica*. He was then treated with emetine-bismuth iodide 3 grains at night (to a total of 30 grains) combined with ten ratren lavages. Frequent sigmoidoscopic examination were made. He has been free from symptoms since the cessation of the treatment (May 1927).

As we well recognize that great caution is required in estimating the value of any particular line of treatment in such a chronic resistant infection as amoebic dysentery, and remembering that similar positive assertions were made about emetine and emetine-bismuth iodide at the time of their introduction to the profession we have refrained from quoting any which have been treated in this manner during the last nine months otherwise our case would be much larger.

The combined treatment has much to be urged in its favour. It has, we think, been abundantly demonstrated that both these drugs possess a definite curative value in amoebic dysentery which may be limited in its extent when they are used singly, but is much more intense when both are combined. We do not think there is any doubt from our observation that ratren is widely absorbed but it may be that it can only reach the amoebic lesion situated in a limited area or the large bowel, and so extensive lesions in the caecum and ascending colon may escape. These lesions and their contained parasites are then reached by the emetine-bismuth iodide given by the mouth. Moreover as the treatment is continuous both by day and by night, the parasite is given no chance to recuperate. Whatever may be said about the rationale of the method, the combined drugs are remarkably well tolerated, and the results as controlled by the sigmoidoscope and backed up by clinical observations, are very satisfactory.

In order to be efficacious, emetine-bismuth-iodide must be prescribed and administered in the proper manner. It is useless, in our experience, exhibiting it in pill or stercoroid form, as is frequently done, since it will be passed out of the bowel unchanged. If covered closely with any protective substance the drug is not absorbed. When given as recommended here it is more nauseating, and is apt to produce its most disagreeable effects. The red powder should be enclosed in a gelatin capsule.

If the full dose is to be tolerated it is better from the point of view of the patient to take one capsule containing 3 grains of emetine-bismuth-iodide rather than three capsules containing 1 grain each. The usefulness of the smaller sized capsule is that the dose can be graduated, and in sensitive persons and in women it is better to commence with smaller doses—1 grain for the first night and 2 grains for the second, so as gradually to accustom them to this drug. Some people cannot tolerate more than 2 grains. It is most important to observe certain precautions in giving the drug. The patient should have had no food or drink for four hours beforehand, and should be absolutely at rest when swallowing the drug. He should endeavour to go to sleep, and any saliva should be wiped from the mouth and not swallowed. Should vomiting ensue within two hours of giving emetine-bismuth-iodide the drug will not be absorbed. In these cases it will be necessary to give 10 minims of tincture of opium out half an hour beforehand. Generally this salt is tolerated at 10 p.m., though in some cases it is difficult, in order to avoid a restless night, to give it earlier—at 6 p.m. When given at 10 p.m. the last solid food should be taken at 4 p.m. and a glass of milk permitted at 6 p.m. Hot applications or surpisms to the epigastrium are useful in prevention of vomiting due to the liberation of the drug from the capsule.

#### *Sigmoidoscopic Appearances*

In connection with this investigation on treatment an intensive study has been made of the sigmoidoscopic appearances of the bowel in amoebic dysentery to supplement previous work of one of us on this subject.<sup>1</sup>

A knowledge of the changes undergone by the bowel in all stages is, of course, indispensable in the diagnosis of intestinal amoebiasis and affords an index as to the cure of the disease by any particular drug or combination of drugs. The lesions differ considerably from those commonly seen on the *post-mortem* table. They are much more minute, delicate, and superficial, so that all the mucosae would necessarily be lost at a grosser *post-mortem* examination. The sequelae of amoebic dysentery and the appearances of the latent stage are, perhaps, the most interesting. In the very acute stages the more dramatic appearances are observed and then fulminant nature must be seen to be realized.

In the most acute stage the superficial nature of the destruction of the mucosa more resembles that of the bacillary dysentery. The mucous membrane is covered with patches of ragged superficial ulceration and dotted with numerous bleeding points and fissures. The bowel surface is much folded and reticulated. When scrapings are made from this haemorrhagic surface, entamoebae are present in masses over the affected area. The lesions extend, as a rule, down the rectum right to the internal sphincter, and are easily visible directly the sigmoidoscope is inserted into the bowel, while the entamoebae may be demonstrated in scrapings taken at random from the mucosa, as in artificially produced intestinal amoebiasis in the cat.

In the subacute stage of amoebic dysentery the bowel surface presents the same folded and reticulated appearance, the lumen is filled with blood-stained mucus, the amoebic lesions take the form of small yellow elevations filled with putty-like material which are probably small ulcerations communicating with the submucosa, while the more recent lesions are represented by small star-shaped haemorrhages in the mucosa. Scrapings from the ulcerated surface yield either scanty entamoebae or Charcot-Leyden crystals which, as J. Gordon Thomson has pointed out, often afford an excellent index of the amoebic nature of the infection.

#### *Chronic Amoebic Dysentery*

Under this heading we have included those cases in which the more urgent symptoms of the disease are absent, and the patient is inconvenienced solely by irregularities of the bowels or by abdominal discomfort. These are just the cases in which the diagnosis is difficult or impossible from the physical examination of the patient or microscopic examination of the faeces for amoebic cysts. Definite ulcerations of considerable size and extent are visible, the ulcers may be superficial, involving the mucous membrane only, or deep and penetrating the submucosa. They usually have undermined edges, haemorrhagic margins, and yellowish or grey bases. On scraping the bases of these ulcers with a blunt spoon masses of amoebae may be recovered in cases where they cannot be found in the faeces.

#### *Latent Amoebic Dysentery*

The sigmoidoscopy is of the greatest practical use in the diagnosis of the latent stages of amoebic dysentery, and it is therefore necessary to be familiar with the somewhat elusive appearances of the bowel. In this case amoebic cysts can neither be found in the faeces nor can the organisms be recovered from scrapings of the lesions. The lesions take the form of yellow papillae on the surface of the mucous membrane, they are associated with the peculiar infolding or reticulation of the mucosa, or the surface of the mucosa may be studded with small pits or depressions which represent healed ulcerations. Intermingled with these, small flame-shaped haemorrhages are often observed. The most deceptive form of all is the one where the only lesions visible are faint and small submucous haemorrhages. The painless nature of the lesions is ascertained by sigmoidoscopy during the more quiescent stages of the disease should be emphasized.

#### CONCLUSION

The lessons conveyed by the study of the different phases of amoebic infection, both in the acute and quiescent stages, should be utilized for the control of the treatment of the disease.

The changes undergone by the mucosa during combined emetine-bismuth-iodide and jation treatment are rapid and striking. A healed bowel after treatment is one in which signs of amoebic activity are entirely absent, but where traces of former lesions are seen in the small depressions or pits which everywhere stud the mucosa, and with which the clinician should make himself familiar as representing a bowel cleansed of amoebic infection. No observations are yet forthcoming to show how long these small and almost microscopic depressions persist, but that they are diagnostic of latent or recently healed intestinal amoebiasis there can be little doubt.

#### DISCUSSION

Professor C. A. Koron (California) said that study in his laboratory during the past nine years of over 4,000 cases of infection by *Entamoeba histolytica* confirmed the greater efficiency of emetine-bismuth-iodide and emetine periodide as compared with emetine, jation, and stovarsol, the last two were useful adjuvants, and neo-arsphenamine was replacing stovarsol with advantage. For diagnosis he relied primarily upon the finding of cysts and the nuclear structure of mature cysts. He had been studying an amoeba which resembled the largest "rice" of *E. histolytica*, and was generally present in the quadrinucleate stage in stools. It had clear pseudopodia in the motile stage, and showed, as its most diagnostic features, a single large lateral blob of peripheral chromatin on the nuclear membrane and the presence of eight chromosomes at nuclear division. In culture this amoeba had maintained its characteristic morphology and behaviour for long periods, in one instance for over a year. The name *Councilmania dissimilis* had been proposed, and the question of pathogenicity or harmlessness was not yet certain.

# RETRO MALLEOLAR TUBERCULOSIS CURED BY TUBERCULIN ADMINISTRATION ACCORDING TO KOCH'S METHOD

ROBERT CARSWELL, M. A., M. B., CH. B.,  
WAND WORTH

When the patient who is here described first came under observation he presented a smooth, soft, uniform, indurated swelling, an inch and a half in diameter, situated between the right internal malleolus and the heel.

The hollow at the sides of the tendo Achillis were filled up and there was some fullness along the outer side of the foot. The swelling was not affected except for one or two papules and a small area the size of a threepenny piece over the lower part of the swelling where it was thin and boggy. There was no pain and no restriction of movement. There was no history of injury; the condition had developed gradually with slight variations during the preceding five years in the last six months of which an oval nodule about an inch in length made its appearance further up the leg just above the top of the boot. The patient was a young farmer, 28 years of age, of good physique and in good health except for an digestive trouble and a rather considerable amount of meridional wear and tear. The condition corresponded to a clinical form of local tuberculosis described by Dr. L. Chido at the British Congress of Tuberculosis in 1904 under the title, "Tubercule retro-malleolaire."

The treatment adopted not only effected a complete cure in the patient but also a permanent cure. The patient began with a 0.002 ccm. and ending in the course of eleven weeks with a dose of 2 ccm. The latter was given at a time to be the full dose recommended by Koch, but at a matter of fact only one-fifth of his maximum dose, which is 20 mg. old solution. The interval between the injections varied from two to six days according to the dose and the proportionate increase of dose was from double with the malik to ten times with the high T. Toleration was very good with the exception of one dose of 0.7 ccm. T.P. administered three days later, 0.3 ccm. when too great an advance caused a sharp reaction which abated within twenty-four hours. The general health of the patient was well maintained throughout the series and even improved. Reaction at the site of dose though distinct was mild although after the last three or four doses there was considerable focal oedema for which the position and movement of the affected part may have been in part responsible.

Six weeks after completion of this treatment the upper nodule had practically disappeared the mass between malleolus and heel had shrunk into a well defined rounded compact lump and the ankle had a much more normal appearance. It was clear that a specific curative effect had been produced and it was noted in particular that in accordance with Koch's description by the time a dose of from half to one milligram had been reached there was distinct clinical evidence of an immunizing action. Ten weeks after the administration of the final dose the effect of old tuberculin was tested 0.0015 ccm. T.H. gave an indurated result 0.007 ccm. four days later was negative but 0.02 ccm. aurum test after a further interval of seven days produced a large general reaction (temperature 102.4) distinct but not excessive focal redness and oedema at the site of dose and great inflammation at the site of injection.

It was concluded from this test that reactionable material still persisted at the site of dose either as living bacilli or their pathological effects. As a matter of fact there were both for fifteen months later the skin over the mass between malleolus and heel broke down giving exit to a necrosed malodorous plug about the size of a marble and having the appearance of coagulated white of egg after which the edges turned in and the site healed soundly and permanently though slowly.

The patient was now too light for about five years. There was then a large area of chronic inflammation of the skin of the length of three in breadth immediately above the former site of dose and a small scrofulous opening ruptured in the lower extension from below upward. Evidently the infection had passed through the aponeurosis near the original site of the disease in the triangular space in front of the tendo Achillis and had spread upward in the subcutaneous tissue. After a few preliminary doses of T.P. bacillary emulsion was given and used on the same intensive plan. The intervals were gradually increased from two days to a much as six weeks and the dose was increased by fractions rather large at first but ultimately not more than a twentieth to an eleventh up to a dose of 3.5 ccm. containing 175 mg. solid and total bacillary substance. This process occupied fourteen months. Mild reaction at the site of dose occurred after the earlier injection and gradual but obvious improvement went on throughout the series ending in complete permanent replacement of the disease by healthy scar formation nine weeks after the last injection. The scrofulous opening was scraped midway in the series without any decisive influence on the course of cure on several occasions subsequent to the scraping fresh places within the affected area inflamed broke down discharged their contents and healed up more or less slowly. With the exception of a little rest occasionally the patient carried out active duties throughout the entire

This case is published not as an example of ideal treatment but as a definite instance of an undoubted specific curative effect of tuberculin corroborative, so far as it goes, of Koch's teaching on the subject.

## OVARIAN HÆMORRHAGE FROM RUPTURED BLOOD CYST

C. C. CHAMBERS, F.R.C.S. (ENG.),

HONORARY SURGEON, ROYAL LEE OF WIGHT COUNTY HOSPITAL.

The account of two cases of severe ovarian hæmorrhage in young girls (*British Medical Journal*, June 18th, 1906, para 657) prompts me to relate a case with similar features and doubtful etiology that recently came under my care.

A young unmarried woman, aged 22, was seen by me in consultation with her doctor about four months ago, for acute abdominal pain which had begun during a game of golf the same day. She gave a history of lumbar ache and vague abdominal discomfort coming on after exercise during the last six weeks. Her period had been regular of four weeks cycle and the next was due.

The present attack consisted of cramp-like pain in the hypogastric and right iliac fossa associated with vomiting. The pulse was 98 and the temperature 100°. The right rectum was lightly rigid, the caecum resembled an apple.

Laparotomy revealed free blood in the peritoneal cavity and altered blood of a thicker consistency and large clot filled the pelvic region. About a pint of fluid was removed. The right ovary was found to be replaced by a dark fleshy tumour three inches in diameter twisted on its pedicle, engorged and ruptured across its centre. The right Fallopian tube was also deeply congested. The tumour and tube were removed and the peritoneum cleared of blood clot and debris as far as possible before final closure of the abdomen. The left adnexal region was examined and the left ovary was found to be lightly congested but otherwise normal. Convalescence was uneventful and the menses appeared regularly and of normal duration.

Three months later I was called to see her again late at night for sudden onset of acute abdominal pain and vomiting which began earlier in the evening. The pain was again cramp-like and situated around the umbilicus and hypogastrium. The temperature was 97° and the pulse 80. The physician pointed to either another ovarian cataplexy or the left adnexa or commencing obstruction of the small intestine from adhesion. The latter appeared the more probable and I set out on opening the abdomen two hours later. A quantity of clear serous fluid gushed out of the wound and examination revealed the lower two feet of ileum distended and twisted round a thin fibrous white band between the intestine and anterior abdominal wall. The wall was divided but the ovary appeared only partially relaxed. A further arch, situated in the right hand higher up connecting the ileum and umbilicus. This proved to be a Meckel diverticulum the canal being patent at its junction with the ileum about two feet above the ileocecal valve. The remainder of the diverticulum which was four inches in length was merely a slender imperforated cord. These bands being suitably divided with the gut grafts returned to normal colour. The appendix being engorged and inflamed was removed at the same time.

The pelvis was now examined. The right adnexal region was clear of adhesion and showed a well defined cavity from the former operation. On the left side a thin wall of ovarian cyst was found. It was freely movable attached by a pedicle and a large as a tennis ball. It was removed without difficulty. The patient made a good recovery. During convalescence she was given a course of thyro-ovarian endocrine compound and various other therapeutics. So far two months after the second operation there have been no symptoms of artificial menopause. On the contrary she is bright, vivacious and of healthy appearance whilst her menstrual flow has occurred since the operation.

There are several features of interest in this case.

1. The pathological report of the solid tumour on the right side showed a mass of blood clot and granulation tissue. There were no signs of ectopic gestation which could be doubted entirely in this case. The condition was probably due to a simple unilocular ovarian cyst that had been subjected to many twists and torsion with attendant hæmorrhages, resulting in final strangulation and rupture.

2. The left ovary though slightly cystic when first examined had become completely degenerated and cystic in the space of three months, and had enlarged to about

three inches in diameter. It would doubtless have shared the same fate as the right ovarian cyst had it not been removed.

3 During this period, menstruation had been normal and regular.

4 The risk of intestinal obstruction was constantly present by reason of the Meckel's diverticulum fixed at either end like a bow-string. This danger became enhanced by the advent of adhesions following the ruptured cyst, the fluid being of a particularly gluey and fibinous nature.

### MEDICAL, SURGICAL, OBSTETRICAL.

#### TREATMENT OF FACIAL PARALYSIS DUE TO EXPOSURE

Facial paralysis due to exposure to cold, often in riding in an omnibus, is by no means rare, I have seen four cases during the last two years.

The great majority clear up quickly under the influence of salicylates and protection from cold by wool, but there are a minority which become chronic, one instance being a woman, aged 70, who had been afflicted since childhood. Undoubtedly such cases would decrease in number if pre-

cautions were taken to prevent the facial muscles from becoming stretched, a line of treatment adopted in other paralyses. In neurological and massage clinics suitable apparatus is used with this end in view, but frequently cases only

reach the clinics when the condition has become chronic.

Two acute cases received salicylate treatment. In another patient a simple splint, made in a few minutes, was used in addition. A piece of covered electrical wire (not flex), about 15 inches long, was bent in the middle and covered with linen tape. The doubled end was bent in the form of a retractor, and inserted in the angle of the mouth. The free ends were curved round the ear in the manner of spectacles, and in such a way as to draw the angle of the mouth upwards and backwards. The device is worn as much as possible, day and night.

The patient volunteered the statement that articulation was easier with the apparatus in position and that it felt more comfortable. Recovery started six weeks later and was almost complete.

#### TREATMENT OF ACUTE TRAUMATIC SYNOVITIS OF THE KNEE

On page 39 of the Army Health Report for 1925 it is stated that where there is no internal derangement cases of synovitis of the knee recover more quickly if treated by aspiration of the joint, repeated if necessary on several occasions. When this operation came into my experience as aspiration was not found necessary, perhaps because my cases were but few, perhaps because they were seen early, perhaps because they were young, but, I venture to submit, it may have been because of the after-treatment by elastic pressure.

I was then serving in the *Excellent*, where there were many young officers and men going through courses of instruction, and it was urgent that any case of synovitis should be cured with the least delay possible. Consequently any joint that seemed to have more than half an ounce of fluid in it was aspirated, the puncture was sealed with collodion, and over this cotton-wool and an elastic bandage were adjusted, producing gentle and uniform pressure, the patient remained in bed, without a splint, though his leg might be swung for two or three days. No patient was away from work more than seventeen days,

and none had to be aspirated twice. In the first eight months of 1908, of the 15 cases of injury to the knee 3 went to hospital (2 with loose cartilages), 1 had a contusion of bone, and 11 had effusion—small in 6, who went to duty in fourteen days (average), 5 had more effusion and were aspirated (fluid 3½ oz. down), they also returned to duty—4 in fourteen, 1 in seventeen days—but of course they were the more severe cases. The first time I heard of this elastic pressure treatment for a superficial effusion Mr. Chiene was telling us of a patient who, on the night before his wedding, boxing with a friend, got a nasty smack in the eye, and came to Mr. Chiene in great perturbation to be saved from an awkward disfigurement on the morrow. Mr. Chiene filled up the patient's orbit very evenly with cotton-wool, put in elastic bandage over, and next day the man was unmarked. Care is required in the adjustment, for haemorrhage occurs wherever in the orbit pressure is relieved by inequality in the packing. The method is most useful, too, in treating sprains, especially if they are seen early, when it prevents subcutaneous laceration of tissues and shortens the time of absorption, it is also useful after operation to limit oozing.

Fleet Surgeon R.N. (ret.)

#### RETROVERTED GRAVID UTERUS WITH INTESTINAL OBSTRUCTION AND RUPTURE OF BLADDER

The following case appears to be worthy of mention on account of its rarity, the complication of rupture and enteritis, and the remarkably rapid improvement of the patient after the intravenous injection of hypertonic saline solution, and of ammonium chloride by the rectum as a preliminary to operation.

On December 15th, 1925, I was called to see a woman aged 32, who was complaining of a sudden acute attack of abdominal pain, colicky in character and accompanied by vomiting. There was no previous history of gastric, biliary, renal, or appendicular trouble, and menstruation had been regular until four months previously, since then she had had no periods and thought that she was about four and a half months pregnant. The bowels acted regularly.

The abdomen was slightly distended and a tumour dull on percussion, was felt above the pubes, passing down into the pelvis. There was no sign of free fluid. Per vaginam, the cervix was felt to be pushed forward towards the symphysis, and a fairly firm mass filled the pouch of Douglas.

The patient was admitted to hospital, and on vaginal examination under an anaesthetic the uterus appeared to be retroverted and fixed in the pelvis. An unsuccessful attempt was made to replace it. On recovery from the anaesthetic abdominal pain with vomiting continued and distension increased. A few hours later the patient aborted a four and a half months foetus, but abdominal distension continued and signs of free fluid were found particularly in the left flank. As distension of the abdomen persisted and the bowels did not move with treatment, exploratory laparotomy was undertaken. The patient's condition at this time was grave, so 3 drachms of ammonium chloride in 5 oz. of water were injected into the rectum, and 10 oz. of a 15 per cent solution of sodium chloride intravenously.

#### Operation

The operation was performed under scopolamine and morphine and local anaesthesia with a little open ether, the peritoneal cavity was found to be full of clear fluid which was mopped up and siphoned off. The small intestine was distended and obstructed by pressure at a point where the posterior inferior wall of the elevated bladder made an angle with the anterior wall of the retroverted and enlarged uterus. Here were some flakes of recent lymph, and here also was a small rent in the posterior inferior wall of the bladder through which urine was passing into the peritoneal cavity. The intestine was easily freed and damaged and the bladder wall sutured. The abdomen was closed except for a rubber drain to the bladder area, and the uterus was brought up from its retroverted position. A catheter was left in the urethra.

For two days after operation the patient had complete anuria, and complained of intense thirst after which urine was passed normally, but very intense and persistent diarrhoea developed and continued for four or five days, during which time she became very ill, but slowly improved and left hospital on January 22nd, 1926, the bladder and bowels acting normally. She has since been delivered at full term of a normal infant, after the newly pregnant uterus had again become retroverted.

Mr. Rutherford Morrison, in *Abdominal and Pelvic Surgery*, mentions rupture of bladder with retroverted pregnant uterus as an emergency, and refers to the occurrence of enteritis following the accident as an extremely rare and dangerous complication. The development of

intestinal obstruction in this case was an interesting complication, especially as its site was at the point of rupture in the bladder

F C PRIMHAM, F.R.C.S.D.  
Honorary Surgeon, Darlington General Hospital

### THE HOT BLANKET PACK IN PERSISTENT VOMITING

ABOUT seven years ago I read in the *BRITISH MEDICAL JOURNAL* an article on treatments for cholera, ending with the remark "On no account forget the hot blanket pack, especially in the case of children." Some time afterwards I was asked to see, in consultation, a boy suffering from uncontrollable vomiting, due to gastritis; the usual remedies had failed, and I recommended the blanket pack. The boy was wrapped in a warmed blanket, and to his body was applied a flannel compress previously wrung out of hot water to which mustard had been added. Food and medicine were stopped. In a short time he went to sleep, and in an hour or so after waking was allowed sips of water, and later, small quantities of liquid nourishment—milk and soda water, etc. I generally begin with sugar and water, and later give milk, with or without soda water, albumin water, and broth, and usually by the third day a gradual return to full diet is possible. In some cases I have used linseed meal poultices with a teaspoonful of mustard added to the first, in place of the compress.

One case was unusual. A girl aged 7 had been ill with chicken pox for a week, and during the last three days had been unable to retain food or medicines, and had got in a critically weak state with sighing respiration, great restlessness, and very feeble pulse. Within three hours of the use of the pack the whole outlook was changed and recovery assured. The next case was a lady who had both eyes operated on for glaucoma the first with local and the second twelve hours later, with a general anaesthetic. When I visited her two days later I found the surgeon in attendance anxious because of persistent vomiting. I suggested the blanket pack and mustard compress, and had a cheerful note the next day to say that all went well afterwards.

So far I have not had a failure with this line of treatment, so thought it worth while pressing it on as an effective and simple means of dealing with other troubles than cholera. In the case of a child one large blanket should be enough in adults two might be used. In any case the object is to secure good surface warmth generally and counter-irritation over the stomach.

Reighier

JOHN B. BERRY, M.D.

### POST-NATAL OSSIFICATION OF THE PARITIAL BONE

As it must be comparatively rare for the membranes over a meningocele to ossify, the following case may be worthy of record.

On June 10th 1927 I delivered a primipara of a male child. The presentation was a right occipito-posterior; the head rotated naturally after a somewhat prolonged labour and the child was delivered easily with low forceps.

The caput appeared to be rather large but at the time this was attributed to the prolonged labour. On the fourth day the caput was still present and was found to be a meningocele. It was fluctuant and translucent, situated at the posterior superior angle of the left parietal and measured 2 by 2 in. being raised about three-quarters of an inch above the surface. The edge of the bone could be felt as a sharply defined ring around the swelling. Apart from the deformity the child was in perfect health and weighed 8 lb. at birth. I naturally felt pessimistic and gave the parent a guarded prognosis.

On July 1st when the child was 3 weeks old a ring of bone a quarter of an inch wide had grown in around the margin of the opening. By July 8th the hole was only one inch across and by July 22nd was completely closed; the new bone forming a hemispheric cover the swelling measuring approximately 1.5 by 1.5 by 1.4 in. It was quite hard not translucent and pressure on it caused the child no inconvenience.

The lesion seems to have been an exaggerated posterior fontanelle. The rapid ossification of the membrane was very striking and seemed to argue the removal of some factor which had prevented intracranial ossification.

Notbury, S.W.

W. EDWARDS, M.B., B.Ch.

## Rebriels

### A NEW TEXTBOOK OF PSYCHIATRY

Drs. D. K. HENDERSON and R. D. GILLIES are jointly responsible for a *Textbook of Psychiatry for Students and Practitioners*. Though the subject-matter and its arrangement are naturally similar to those which are customary in manuals of psychiatry, this volume has a distinctive "atmosphere" of its own, and we feel that its authors have been justified in providing yet another textbook on mental disease.

The first chapter consists of an interesting historical review of the cure and treatment of mental illness, and the second deals with classification. The authors point out that no attempt at psychiatric classification is entirely satisfactory, and consequently "that diagnosis" or the placing of the patient in an appropriate class is on an unstable foundation. It is not diagnosis which matters, however, but the understanding of the disorder, and the patient who suffers from it—under what circumstances it arose, how it is related to the patient's normal condition, what the disorder means, what light is shed on his problems and what can be done to help towards a favourable outcome. The authors—with considerable justification it would seem—renounce the rigid notion of disease entities, speaking of the different types of mental disorder as different "types or reactions." Disease, whether physical or mental, is not, as we know, an entity or "thing" with an independent existence of its own; it is a process—a reaction of the living organism to conditions which tend to disintegrate it. Thus general paralysis is merely a convenient term to include some of the reactions which result from no action of the syphilitic virus upon the organism. It is only one of the many types of reaction which may be exhibited, for the nervous system may be affected in numerous ways without adversely influencing the psychic reaction, and when the latter is affected as in general paralysis the clinical forms of this malady are infinite in their variety. It is in mental diseases particularly that we observe how variable are the reactions of the living being to the same noxious influences.

The scheme of classification adopted in this volume is simple but adequate. After chapter dealing with etiology, method of examination and general psychopathology, we are given a clinical description and modes of treatment of the affective (manic-depressive psychosis) and involuntal (melancholia), schizophrenic and paranoid reaction types. These are followed by chapters on mental defect, psychoneuroses and the psychoses and psycho-neuroses of war. The volume includes a practical account of occupational therapy and also a chapter on psychiatry and the law. The latter includes an account of the law in Scotland relative to the admission of voluntary boarders and certified patients into mental institutions.

A valuable feature of this book is the large number of clinical records of the writers' own case. In their preface they state that they have done this for the following reasons: since mental illness is an individual affair its symptoms have but little meaning apart from the setting in which they occur. This setting includes not only the general mental and physical condition at the time, but the individual's personality, circumstances and history from his earliest days. Hence general descriptions of clinical syndromes while interesting are not of the first importance. What is wanted always is an understanding of the patient as a human being and of the problems which he is meeting in a morbid way.

Unfortunately many psychiatrists feel the main "problem" which the psychotic patient has to face is a morbid change in his organism—in the depths of his organic life—which manifests itself by morbid intrusion into his psychic life. This morbid change—the patient's problem—he certainly cannot control, and he is even unaware of its existence. In only too many cases the

*A Textbook of Psychiatry for Students and Practitioners*. By D. K. HENDERSON, M.D., and R. D. GILLIES, M.D. Clarendon Press, Oxford. 1927. (Demy 8vo pp. x + 502 12s. 6d.)

psychiatrist also is unable to control or prevent the morbid events taking place in the organism, and our knowledge of their nature is still very meagre. Hence our relative incapacity to apply precise therapeutic remedies in the biogenetic psychoses, and the urgent need for continued biological research.

The views expressed in this admirable volume are largely inspired by the teaching of Professor Adolf Meyer. Due acknowledgement is made by the authors, who have dedicated their book to this eminent American psychiatrist.

### SURGICAL ANATOMY

THE appearance of a third edition, apart from three reprints, of *A Manual of Surgical Anatomy*,<sup>2</sup> by Mr. BEESLEY and Professor JOHNSTON, within the short period of eleven years affords unimpeachable evidence of the high esteem in which the book is held. Its success is in no way surprising, for in scope, in clarity of expression, and in accuracy of statement it leaves little to be desired. In view, however, of the important position it has obtained among students' textbooks and of the certainty that further editions will shortly be required we propose, while recognizing the manifold merits of the work, to point out certain small details to which we venture to take exception.

We see, for instance, no necessity to represent the relationship of the tendons of the flexor sublimis digitorum in Fig. 31 inaccurately, diagram though it be, and we consider the term "middle palmar space" puzzling and meaningless, unless both the thenar and hypothenar spaces are mentioned. In Fig. 82 the perinephric fascia and the fascia over the psoas of one side are shown passing across the middle line to become continuous with the corresponding fascia of the opposite side in a way to suggest that use on one side would almost inevitably spread to the other. On page 277 these two fasciae are, to say the least, clearly distinguished, a view which, unfortunately, is affirmed in Fig. 83. On page 315 the cystic artery is stated to cross in front of the common hepatic duct, a relationship which we believe to be the exception rather than the rule. On page 271 the sessile hydatidiform body of Morgagni is alone mentioned. In the account of the lymphatics of the mammary gland nothing is said of the lymphatics of the nipple, while among the vessels drained by the superficial inguinal glands the body of the uterus fails of recognition. More important omissions affect the sphincter round the common biliary and pancreatic ducts (Oddi's) and the various sphincters of the alimentary canal, other than the pyloric and ileo-caecal. With the exception of Jackson's vein no mention is made of the occasional peritoneal folds found passing between neighbouring abdominal viscera, of which some five or six are now recognized. The site for injecting the second division of the fifth cranial nerve is given, but those for the first and third divisions are ignored. Turning from such details to a matter of more general character, we consider the book would gain considerably by a less rigorous exclusion of physiological reference. The authors apparently are not unaware of this, for in the section dealing with the sympathetic and parasympathetic systems they depart in some measure from their self-imposed rule.

The book naturally invites comparison with the other English textbook on the subject—namely, TIERES'S—but it is a comparison into which we prefer not to enter. Each book will no doubt have its own adherents, perhaps in equal numbers. We will content ourselves with saying that in our opinion Beesley and Johnston's manual is more to the anatomical side, Tieres's more to the surgical side of the subject. In one important respect—namely, in illustrations—the former book is far superior, the skidgrains of the abdominal region being of quite special excellence. In conclusion, we would say that the book is well on its way to becoming—if it has not already become—a standard textbook, it reflects the highest credit on its authors.

*Manual of Surgical Anatomy* By Lewis Beesley, L.R.C.S.E. and T. B. Johnston. Third edition. London: Milford Oxford University Press, 1927. (Cr. 8vo pp. xiv + 565, 165 figures, 18 net.)

### THE ENGLISH PUBLIC HOUSE

MR. ERNEST SELLEY remarks that it is strange that no one has yet attempted to give any comprehensive survey of the public houses of the country. They are much talked of, often with laud epithets, many who comment on them would appear to have little or no knowledge of them personally. He therefore set himself to learn their character first-hand. He spent two years on his investigations, visited many types of towns and country districts, and from his experiences has produced a very readable and informative book, *The English Public House as it is*.<sup>2</sup> There are over 80,000 public houses in the country licensed by the justices for the sale of intoxicating liquor. The public house is more than a shop. It is a place where people busy for social intercourse as well as for refreshment. They busy in a fashion that no one does in a tearshop. Yet the history of the licensing laws shows that successive generations have regarded the public house as a potential danger to the public well-being. The Privy Council in 1604 said, "ale-houses and victualling houses ought to be no more than a number competent for the receipt of travellers, and for the supply of wants of poor people not able to provide for any quantity of victual for themselves (which is the true and natural use of these houses)."

Public houses, formerly owned by tens of thousands of separate individuals, are now so few as nine-tenths of them owned by a comparatively small number of brewery companies. They are multiple shops, as business organizations, to judge by the balance sheets of the companies, they are highly successful. As a firm of stockbrokers put it, "In good trade or bad trade, whether there is a strike or whether there is a lock-out, the brewer always makes money." The manager of a house may be good from the public point of view or from the trade point, the two are not synonymous. An undesirable back-street house is often a better commercial proposition than a more up-to-date house in a main street.

Mr. Selley's experience convinces him that the overwhelming mass of the people who use the public houses (and they form well over half the adult population) is not in the least besotted or degraded. The bulk of its patrons seek companionship. Generally there is good feeling both sides of the bar. There is companionship, refreshment, enjoyment, warmth, and light. A man seeks his "set", they talk on things that interest them—even Bernard Shaw and the relative values of paper and sterling! "The 'pub' is the working men's club", but there is evidence of a demand for a better club in the increasing number of clubs in towns, some of which have definitely come into being because of discontent with certain public houses. Drunkenness is mainly seen at week ends when there are funds in the pocket and a greater concourse in the public houses. The Saturday night swilling is difficult to account for on any rational grounds in civilized communities. Statistics of drunkenness the author finds unreliable as a basis for argument. The methods of the police vary in different parts. He cites some examples. The following is a good one. Huddersfield has one licensed house for every 362 people, Middlesbrough one for every 757, yet the number of charges for drunkenness per 1,000 people in Middlesbrough in 1924 was seven times that of Huddersfield.

Public houses vary greatly in type. Some are frequented by definite groups. Men meet for business or market purposes. Some have a name for being frequented by bookmakers, others by loose women. If these are disturbed by the police the customers fit to fresh quarters. As taverns, for the supply of food, there is still much business done, particularly in market towns and in great centres of population. Some, by supplying good food at rates that underest local restaurants, attract a large custom and pay well, on the policy of strengthening the spirit to catch the whale. Others have developed a social side, the house has a bowling green or a quoit pitch. It may be the headquarters of a football club, pigeon club, cycling club, or the like. Entertainment clubs are formed and have their headquarters in the public houses. Large numbers of trade union branches hold their meetings in public houses, which

*The English Public House as it is* By Ernest Selley. London: Longmans, Green and Co., Ltd. 1927. (Demy 8vo, pp. v + 184, 5s. net.)

give rooms for meetings free of charge. The local institutes which make a charge of 5s. for such facilities are beaten by the public house which takes its part in other forms. The author visits many evening entertainments, as one of the company and describes his experiences.

True the entertainments bordered on the verge of profanity and much of the patter was very suggestive. The people love community singing. A chorus about "I know the loves me here" she told me was sung again and again with great spirit. There was no doubt that while singing these people were happy. Their faces were transformed and their eyes shone with delight. Tired and suffering had made their mark on the faces and bodies of many of the women. The only beautiful thing about most of them were their eyes during the singing. Their voices were not pretty but their eyes were like jewels.

Where no music licence is allowed the wireless has made up for the lack. In one of the best houses in the Potteries which had no music licence the barmaid said, "We don't want one now, it would attract the riffraff." But there is a wireless behind the bar. The barmaid said that on Sundays the customers like to hear the church service. "They simply love to hear the hymns and sermon, and they sit absolutely quiet while it is on." There are signs that the village public house is deteriorating. Much of the former Saturday night custom goes into the small towns, the motor bus is responsible for this, and the attraction of the pictures. In isolated villages there are as much a part of the established order of things as the church, and it is no uncommon thing to hear a mandolin Saturday night violinist singing lustily in church on Sunday morning.

The author notes defects and abuses, the demand for reform, the experience of the Carlisle scheme, efforts of reform by the trade, the growth of the public house habit among women. He asks the question, "Have public house habits improved?" He is very cautious in his reply. It is, he says, difficult to get a fair criterion of what former conditions were. While he finds general agreement that there is better behaviour and less excess nowadays, very few would commit themselves to the assertion that the number of people who take intoxicants in public has decreased. In his opinion the greatest checks on excess have been restricted hours of opening and high prices. These two factors combined with a lower average specific gravity have resulted in producing a measurable decrease in the amount of drunkenness. Longer hours and lower prices, other things being equal, tend to increase consumption and drunkenness, though perhaps not in the same proportion as formerly.

On the larger questions of policy his conclusion is this: "The community has seen fit to restrict this business and limit its power to injure by means of laws and regulations but until the great pushing power of private profit-making has been removed the community cannot expect to be master in its own house." It is a book to read.

### THE NATURE OF DISEASE

Part I of Mr J. F. R. McDonagh's *Nature of Disease* was fully reviewed in these columns on its appearance three years ago (November 29th 1924, p. 1008) and now he has brought out Part II, which in due course is to be followed by another dealing with intestinal auto-intoxication and chemotherapy, the genesis of cancer and other problems, and correlating with medicine recent psychological work and Mr F. M. Alexander's views on the conscious control of the individual.

The present instalment, the appearance of which was delayed by the destruction of the type by fire, is therefore part of an encyclopaedic work and commands respect for the author's imagination, enthusiasm and energy. The difficulties of judging fairly the future possible applications of physical chemistry to medicine are very great in the present state of medicine, but important modifications in the basal conceptions of the mechanism of life and disease must be imminent in the light of the

advances in connexion with the constitution of the atom and the electron. In the first chapter Mr McDonagh considers the characteristics and changes which the protein particles in the plasma undergo in disease. These are summed up as (1) dispersion leading to coagulation, and (2) condensation with subgroups of (a) hydration and (b) dehydration and gelation. The next chapter details the influences of the changes in the protein particles on the concentration of water and inorganic salts in the blood, hydration, or gelato-hydration leads, it is said to hydraemia. It is maintained, further, that when undergoing gelato-hydration the protein particles become precipitated in any one or more of the four important viscera in the following order—kidneys, brain, lungs, and liver, damming up of the glomeruli causes parenchymatous nephritis and profound hydraemia and oedema, and the author is firmly convinced that the so-called chloride retention has not anything to do with oedema. Arhydraemia is the result of dehydration of the protein particles which become soluble, thus increasing the "solid" contents of the plasma; this it is said, leads to hardening of the capillary walls and interstitial changes, arteriosclerosis, and fibrosis of the viscera. In later chapters the changes in the vascular system and in the viscera resulting from alterations in the state of the protein particles are considered in detail and, as elsewhere, illustrated by cases. The genesis of cancer, considered in Part I in three chapters, is again submitted to critical analysis in the light of Gre and Brinard's work, and the somewhat remarkable conclusions are drawn that that work favours the non-parasitic rather than the parasitic origin of cancer, and that "the cause of cancer will never be found because as an entity it does not exist."

The concluding chapter of ninety pages is concerned with chemotherapy, organotherapy, and immunotherapy. Which it is held, increase the bodily resistance by subjecting the protein particles in the plasma generally, and in the leucocytes locally, to division and subdivision, thus augmenting the area of proteolytic substrates exposed to the invader for it is regarded as certain that therapeutic preparations do not exert any direct action on invader, their first action being always on protein particles in the blood stream. Further, it is laid down that no therapeutic substance acts primarily on a specialized structure, for example, "the sympathomimetic action of adrenaline is secondary to the dual action of conduction and dehydration exhibited by this drug upon the protein particles in the blood."

As was the case with Part I the work is far from easy reading, and it is rather striking how very little reference is made to the researches of other writers within the wide area of subjects on which Mr McDonagh touches.

### ORTHOPAEDICS OF CHILDREN

The volume entitled *Orthopaedics of Childhood*,<sup>1</sup> like the others of this series is intended for the general practitioner. It will probably be found by him to be a useful guide to modern methods of treatment of deformities in childhood. The title would have been pleonastic when orthopaedics were restricted to the etymological meaning of the term, as used by its inventor, Andry.

Dr WILLIS CAMPBELL is known as a capable surgeon, well acquainted with his specialty and this book will not do him or the University of Tennessee discredit. In his preface he expressly disclaims any pretensions to a complete representation of the literature or of the evolution of this vast subject. The object of operative method alone is considered consequently many standard procedures are barely mentioned or omitted.

With the limitations above implied this book will doubtless be found useful. Unlike surgeon of the Boston school the author scarcely mentions posture or the supposed results of faulty posture. There are many illustrations but some of the reproductions of photographs are by no means satisfactory.

<sup>1</sup>The *Nature of Disease*. By J. F. R. McDonagh. F.R.C.S. Part II. London: W. H. Freeman (Medical Books) Ltd. 1927. (Cr. 4to pp. 344. 12s. net.)

<sup>2</sup>*Orthopaedics of Childhood*. By Willis C. Campbell, M.D., F.A.C.S. Chicago: Lippincott Co. 1927. (Cr. 4to pp. 344. 12s. net.)

One of the drawbacks of a series such as this, to which Professor Foote's *Diseases of the Bones, Joints, Muscles and Tendons*,<sup>6</sup> also belongs, lies in the difficulty or even impossibility of avoiding overlapping of subjects. We find in Dr Foote's volume articles on quite a large number of subjects which are also treated of by Dr Willis Campbell. This may be accounted for by the statement in Dr Foote's preface that his book "treats of disease as affecting these tissues and structures from the point of view of the physician rather than that of the surgeon." Certainly the paucity of details of surgical treatment bears out this statement. We believe that any attempt to divide orthopaedists into physicians and surgeons is wrong. The orthopaedic surgeon should know all be, in the words of Jonathan Hutchinson, "a physician who operates," and the establishment of two points of view can only be bad for the patient. Everyone who treats Pott's disease, for instance, uses fresh air and sunshine and good food as well as jackets and extension frames, and all surgeons give cod-liver oil for rickets as well as applying splints or the osteotome. The outlook for the practitioner is gloomy if he is to find himself obliged to study two works on every surgical subject—one written from the physician's point of view and another from the surgeon's. Many subjects are considered in this volume which, as far as we know, are not susceptible of any so-called medical treatment. What, for instance, is the medical point of view in the treatment of congenital and developmental anomalies of the bones, or of congenital defects such as dislocation of the hip, talipes, cleft palate, and supernumerary digits, to mention a few conditions? On the other hand the article on rickets contains a great deal of information on the present state of opinion on the etiology of this disease, although the author seems not to find it necessary to quote recent British investigators of this subject.

### NOTES ON BOOKS

THE importance of scientific method in malaria survey work has sometimes been neglected, and factors of first-rate importance have not been recognized. One of these—namely, the enormous loss of time and labour involved in hatching out larvae of anophelines as a preliminary to identification—has received attention by Drs STRICKLAND and CHOUDHURY in *An Illustrated Key to the Anopheline Larvae of India, Ceylon, and Malaya*,<sup>7</sup> which is a sequel to the *Short Key to the Adult Anophelines* by the senior author. It deals, therefore, with larval forms, methods for their collection, transmission, preservation, and examination, and contains a key to the identification of the oriental species, some fifty in number. In appendices reference is made to the necessary equipment and staff, the recorded geographical distribution of the species, and the commoner habitats of the larvae. The book will prove of great value to all those engaged in malaria survey work.

*Tuberculosis*,<sup>8</sup> by BALDWIN, PETROFF, and GARDNER, deals chiefly with the bacteriology and laboratory diagnosis of the disease, and is intended to serve the needs of teachers, students, laboratory investigators, and technicians in tuberculosis institutions. The chapters devoted to the acid fast group of bacteria, the biology and diagnosis of *B. tuberculosis*, experimental tuberculosis, pathological anatomy, serum diagnosis, tuberculin and experimental therapy, describe the procedures which the authors have found the most useful, and should prove of special value to laboratory workers. The book is excellently illustrated with numerous original drawings and photographs and four coloured plates.

Dr G. O. LOTS's book on *The Radiographic Diagnosis of Bilharziasis*<sup>9</sup> is a collection of skilful photographs showing the infiltration of calcified bilharzian eggs in the bladder, uterus, and kidneys, accompanied by a discussion in French, English, and

Arabic on the parasites, the infiltrations, and the differential diagnoses—more especially from urinary calculus. The photographs have been made mostly from cases sent to the author for examination for suspected calculus. The cases are discussed in detail, and the photographs are interleaved with explanatory diagrams. The statements about the parasites in the introduction are scrappy, but the volume should prove of considerable value to those interested in radiology, especially in a country such as Egypt, where two thirds of the population are infected.

It is often said, particularly in introductory addresses at this season of the year, that it is a good thing for a medical man to have a hobby. Mr JOHN W. WEIR, helped perhaps by the clear skies of South Africa, has found a hobby in astronomy, especially in the study of comets. Like others before him, he is puzzled to account for the constant form a comet maintains, and in a book, *Comets and the Sun*,<sup>10</sup> he has put forward a theory which would attribute the form to the presence of an envelope. The study of comets led him to consider theories and known facts with regard to the sun, and he has a chapter on the solar origin of the planets. The book is beautifully got up, it is a quarto, and its form has no doubt been selected in order to make possible the reproduction of a number of large photographs—some of them lent by eminent astronomers—of comets and of the sun, they are extremely well presented. One of them, in colour, of a great scarlet solar prominence is very striking. The frontispiece is a photograph of Halley's comet, lent by the late astronomer at the Cape, and on another page there are four photographs of the same comet taken at the Transvaal Observatory in 1910. We have no doubt that the book will be found of interest by those among our readers who are attracted to the study of the heavens.

To *The Tibetan Book of the Dead*,<sup>11</sup> which the Oxford University Press has published (price 16s.) for Dr W. Y. EVANS WENTZ, belongs the respect which attaches to a writing looked on as sacred by at least one part of a very large section of mankind. The title is no doubt correctly translated, but the scope of the book might perhaps be better conveyed by substituting 'death' for 'the dead'. To read the translation itself, made by a Tibetan Lama acquainted with English, one must be something of an enthusiast, primarily it is a service to be recited to the dying, it fills 160 pages—nearly two thirds of the volume. Dr Evans Wentz has written an introduction filling 80 pages, which is an essay on Buddhist doctrine. Sir John Woodroffe, Reader in Indian Law at Oxford, has provided a foreword giving an explanation of the doctrine implicit in the ritual, in the course of it he makes the observation that the fundamental difference between Christianity and both Brahminism and Buddhism is that the former teaches resurrection and the latter reincarnation. To those attracted by the study of what is sometimes called comparative religion the book will prove interesting.

<sup>10</sup> *Comets and the Sun. New Theories Regarding Their Structure.* By John W. Weir, M.D. F.R.C.S. Ed. London: Longmans Green and Co., Ltd. 1927. (Demy 4to pp. xv + 72 illustrated. 12s. 6d. net.)

<sup>11</sup> *The Tibetan Book of the Dead, or The After Death Experiences on the Barid Plane* according to Lama Kazi Dawa Samdrup's English Rendering. By W. Y. Evans Wentz, M.A., D.Litt. B.Sc. With foreword by Sir John Woodroffe. London: Milford, Oxford University Press. 1927. (5½ x 9 pp. xiv + 248 illustrated. 16s. net.)

### PREPARATIONS AND APPLIANCES

#### 1 Standard Ether

MANY years ago a distrust of ether as an anæsthetic became engendered in the public mind as well as among the medical profession. The suspicion was no doubt originally well founded, for in earlier days the finer degrees of purity, if not quite unknown, were more rarely attained, certainly no sharp discrimination was exercised between the purest and the ordinary. It is now known that all the defects peculiar to ether were due to a group of impurities some of which originated in the process of manufacture, others—such as peroxides—being generated through exposure to sunlight during storage. Echoes of the old distrust from time to time are, however, still heard, more particularly in the lay press. Popular prejudice may do much harm, and should be corrected at every opportunity. It deserves to be made known that in twelve years 500,000 pounds of ether for anæsthetic use have been supplied by Messrs. Howards and Sons without the report of any untoward event. Messrs. Howards and Sons are manufacturers of a highly purified ether for anæsthetic use which they supply in amber coloured bottles under the label of Howards Standard Ether. We have examined a specimen analytically, with results confirming the makers' claims as to its purity.

<sup>9</sup> *The Radiographic Diagnosis of Bilharziasis.* By Dr G. O. Lots. Paris: H. Fricke and Co. 1927. (Med. 4to pp. 90. 22 plates, 83 figures. 25s. post paid or 50 francs.)

## THE STATE OF THE PUBLIC HEALTH

## SIR GEORGE NEWMAN'S REPORT FOR 1926

ENGLAND AND WALES

[Concluding Notice.]

## CANCER

The death rate per million of the population in 1926 due to cancer was 1362 as compared with 1,556 in 1925 1297 in 1924 and 1267 in 1923. The point is reiterated that these figures do not indicate an actual rise in incidence but that important factors in the apparent rise are more accurate diagnosis improved certification of the causes of death and increased longevity resulting in a greater number of people reaching the age period of cancer than was formerly the case. It is suggested that the hope for the future lies in the discovery of some biochemical test which will render possible early and accurate diagnosis, together with the provision of some method of treatment other than surgical, and some etiological revelation which will open the way for prevention. Details are given of the work of the departmental committees the main facts that have been established, and the reports that have been issued. The compilation and study of accurate records are mentioned as a desideratum, and reference is made to special events during 1926 such as the success of the Yorkshire Council of the British Empire Cancer Campaign in collecting money and founding the research centre at Leeds. The depth of the public interest was recognised practically by the British Medical Association, which devoted the Hastings Lecture for 1927 to this subject.

## Tuberculosis

Sir George Newman has still to complain that in some districts a considerable proportion of tuberculosis cases are not notified before death. The decline in the mortality of this disease continued, the number of deaths from pulmonary and other forms being respectively 50,108 and 7,417 in 1926 as compared with 52,382 and 8,005 in the previous year. The reports of medical officers of health show that in many districts accommodation for advanced cases remains inadequate but more facilities have been introduced for dealing with surgical tuberculosis and co-ordination has improved. The diagnostic value of x-rays has been increasingly recognized and the use of artificial light treatment for various forms of tuberculosis including lupus has been extended. There is more co-operation between general practitioners tuberculosis officers, Poor Law authorities, and school medical officers. It is suggested that it would be well if the annual reports by medical officers of the urban and rural districts contained fuller information about the conditions in their areas as regards this disease in view of its preventability, there seems to be general agreement that unsatisfactory housing conditions play a large part in its prevalence. Mention is made of the sanatorium and Spralinger methods of treatment and Sir George Newman regrets that in the latter case the complete serums and vaccine have not been available for a scientific investigation of their clinical efficacy by the Ministry of Health. Approved x-ray facilities have been provided by 37 county councils and 48 county boroughs under their tuberculosis schemes, and the value of radiography in diagnosis and in the estimation of progress is generally admitted.

## Venereal Disease

At the close of 1926 there were 190 treatment centres in England and Wales, with approximately 770 weekly sessions. A tabular summary of the returns from these centres for the last ten years indicates a slight decline in syphilis but more cases of soft chancre and gonorrhoea were reported. The ratio of attendance to cases showed a further increase in 1926 implying a reduction in the amount of debility before the completion of treatment; this is attributed to the propaganda work of the British Social Hygiene Council and local authorities and to the

influence exercised by the medical officers at treatment centres. There is no evidence that the establishment of centres in special premises apart from general hospitals deters patients from attending. The suggestion is made that the reduction in the number of cases of syphilis would be more pronounced if there was not inadequate treatment by some practitioners which results in relapse and the appearance of the patient at a treatment centre as a new case though not a fresh infection. It has been shown that the short course of six or eight injections of an arsenobenzol compound and mercury is followed by a high percentage of relapses. The importance of early diagnosis and treatment of syphilis in pregnancy and in congenital cases is emphasised.

## Maternity and Child Welfare

A striking feature of this section of the report is the conclusion that the general financial stringency of 1926 did not cause any appreciable physical deterioration in children. This is attributed to the special efforts made to sustain their nutrition by the provision of meals at schools, the increased amount of milk supplied to nursing mothers and infants, and the activities of the officers of local authorities and voluntary workers. More facilities are now being made available by maternity and child welfare authorities for consultations with specialists, institutional treatment and nursing assistance in cases of puerperal pyrexia. The number of maternity homes and hospitals recognized by the Minister of Health, either directly or indirectly, for purposes of grant is voluntary institutions 81 with 1,423 beds, and municipal institutions, 68 with 857 beds. Emphasis is again laid on the importance of ante-natal supervision, and it is stated that there are now 772 centres for this, as compared with 675 in 1925. Infant welfare centres have similarly increased from 2,195 to 2,324, but the large average attendance at these indicates that still more are required. There are now 3,963 whole-time or part-time officers engaged in health visiting, and a reminder is given that on and after April 1st, 1928 all health visitors appointed for the first time will be required to possess the certificate in health visiting approved by the Ministry. The case of the child between the ages of 2 and 5 remains a problem still awaiting satisfactory solution. As a result of the examination of nearly 1,000 children aged 3 in various parts of the country it was found that in 48.7 per cent. there were manifestations of rickets. Dental decay was noted in 21 per cent, enlarged tonsils in 21.7 per cent, a denture in 15.3 per cent. Sir George Newman refers to the international inquiry into infant mortality which was instituted by the League of Nations in 1926 with special reference to (1) immunization against diphtheria, scarlet fever and measles, (2) the provision of instruction in pediatrics for medical students, nurses, midwives and health visitors, and (3) the investigation in selected areas of different countries with regard to the causes of infant death. It is hoped that among other good results this inquiry will stimulate interest in child welfare among the more backward communities and lead to improvement of the prophylactic machinery.

## The Insurance Medical Service

The total population of England and Wales in 1926 was 39,067,000, and 14,102,000 persons were entitled to medical benefit under the National Health Insurance Act. The number of insurance medical practitioners was 14,432, and the average number of insured persons on a practitioner's list was 945. The total cost of medical benefit in the year was £5,621,638 of which approximately £6,592,500 was devoted to the remuneration of doctors, and £2,228,738 to the provision of drug and appliances.

## Regional Medical Staff

The regional medical staff consisting of fifty-one whole-time medical officers dealt with 390,487 cases in 1926, as compared with 204,088 in the previous year. This large increase was almost entirely due to references by approved societies on the question of incapacity for work during the period of the coal stoppage.

*Health Education by Insurance Committees*

It appears that 75 of the 128 Insurance Committees in England undertake health education work to some extent, and in 33 years its scope may be termed considerable. The methods employed included public lectures, cinematograph and lantern demonstrations (21 committees), lectures by insurance practitioners to persons on their panel lists (12 committees), distribution of literature and publication of posters (42 committees), and participation in exhibitions and health week campaigns (25 committees).

*Food in Health and Disease*

Sir George Newman throws doubt on the current view that primitive man was more favourably situated as regards his diet and nutrition than the man of the present day, but he admits that the diet of a considerable proportion of the population is not nutritious enough. He discusses entirely various popular beliefs about nutritive values, and emphasizes the importance of milk and green vegetables. The gratifying progress that has been made in checking adulteration of milk and butter is shown by a chart, this is attributed not only to legislation, but also to a better informed and more determined public opinion. Reference is made to the possibility of arsenical contamination of apples and of glass fragments in food, the new regulations with regard to the use of preservatives have been actively applied. Numerous outbreaks of food poisoning occurred during the year, but none were on any considerable scale.

*Scientific Investigations*

One department of the Ministry of Health is engaged in the collection from home and abroad of medical information, and arranging for its transmission to appropriate quarters, it collaborates closely with the Epidemiological Bureau of the Health Section of the League of Nations. In the Ministry's pathological laboratory the preliminary work on the serological classification of hemolytic streptococci has been completed, and a report published in the *Journal of Hygiene*, 1926, vol. xxx. The study of pneumococcal virulence and immunity is approaching completion, and forty-eight outbreaks of food poisoning were investigated during the year. Professor Topley and his assistants are continuing their study of the flora of the respiratory tract in the hope of elucidating some of the problems of epidemic influenza.

*Artificial Light Treatment*

Increased provision was made during 1926 by local authorities for artificial light treatment in connexion with tuberculosis and child welfare schemes. An account is given of the results obtained by the use of various types of lamps. The importance of skilled medical and nursing supervision is emphasized, and the indiscriminate use of ultra-violet rays is strongly deprecated.

*International Health Co-operation*

Sir George Newman devotes one chapter to the consideration of health questions from the international point of view, and describes the organization and work of the League of Nations in this respect. An international standard of potency has been established for diphtheria and tetanus antitoxic serums, and tuberculin has been similarly considered. Interchange courses of instruction for public health officers were continued, and have now been extended to Japan and West Africa. Two special tours were arranged to maritime ports in the Mediterranean, the Baltic, and the North Sea. The weekly bulletin of infectious diseases in the East has proved very useful to the public health administrations concerned. The International Office of Public Hygiene in Paris has prepared a revised draft of the International Sanitary Convention of 1912 and has completed its work on the nomenclature of disease. Useful interchange of information has been arranged with regard to small-pox, scarlet fever, encephalitis lethargica, relapsing fever, typhus, and yellow fever. Details are given in this section of the report of the important international sanitary conference held in Paris

during May and June, 1926, and reference is made to the valuable scientific papers read at the International Pacific Health Conference in Melbourne last December.

*The Way to Personal Health*

Sir George Newman concludes his report with a very interesting and stimulating summary of the general health position. He indicates what the State is doing to stimulate and reduce premature mortality, and insists that a sanitary environment is the essential basis of all effective medical services. He shows that in spite of an enormous increase of population without enlargement of the home territory the total death rate and the infantile mortality rate of the nation have been halved within four generations. Moreover, the mortality of childhood is one-third of what it was eighty years ago, and the expectation of life for a child born in this country to-day is no less than seventeen years longer than it was for a child born in 1846. His brief but comprehensive account of the campaign against small-pox on page 261 of the report may be cordially commended to the attention of those exposed to the inquiries or criticism of the ignorant or fanatical opponents of vaccination, it provides a veritable armoury for the busiest medical practitioner. The preventive value of health insurance is similarly displayed, and the way to personal health is clearly and convincingly indicated. After showing how recent years have been characterized by many improvements in the public outlook on life, Sir George Newman ends his report with the following two sentences:

"These changes indicate an immense awakening and a wider use of the improved environment and health facilities which the State has provided. Much disease and impairment remain, but evidence and experience suggest that we are on the high road to their amelioration."

## UNIVERSITY OF CAPE TOWN

## NEW MEDICAL SCHOOL BUILDINGS

## [FROM OUR SPECIAL CORRESPONDENT]

THE first of the two blocks comprising the new buildings for the medical unit of the University of Cape Town, the foundation stone of which was laid by the Governor-General, the Earl of Athlone, on May 10th, 1925, has been completed and is now occupied. The buildings are situated near the Mowbray entrance to the Groot Schuur estate, at a distance of exactly one mile from the main university, which is now in course of erection on a site which can only be described as majestic in its surroundings and outlook. The medical school itself is distant some three miles from the city proper, from which it may be reached by two alternative routes—by the de Wail Drive, the mountain motor road skirting the foot of Table Mountain and the Devil's Peak, or by way of the main road leading from the city to its southern suburbs. The buildings of the medical school are quite close—to be precise, some two hundred yards—to the site for the new General Hospital, which is now being cleared and levelled on the slopes just below the de Wail Drive. The medical unit will thus be very closely associated with the hospital, an association which clearly is in the interests of the patients as well as of the research to be carried out in the several departments.

The block completed, to be known as the Weinher-Beit block, is from the design of Mr. Cleland of the public works department, and is in the shape of a double "E," with the central portion omitted on the western, or de Wail Drive, side. It is a stately and imposing building of stone and concrete, standing in surroundings that give promise of ultimately becoming a fine terraced park. The main entrance is from the de Wail Drive side and gives immediate access to the three floors—a basement, a ground and a first floor—which are readily reached by a central stairway. A feature of architectural interest is the central courtyard extending from the basement to the top of the building, which serves the dual purpose of lighting and ventilation. Opposite the main entrance, and occupying the middle projecting limb from the main horizontal

corridor, are the three lecture theatres, placed one above the other. On the first and second floors are the two main theatres, each with accommodation for about two hundred students. The seating is arranged in semicircular fashion on ascending tiers. The lecturer's desk is fitted with facilities for the demonstration of specimens and behind it, on the wall faced by the audience, are double sliding blackboards and an adjustable screen for the epidiascope, one of which of the latest pattern is provided in each theatre. Ventilation is efficiently carried out by a system of powerful double-acting electric fans by means of which a continuous current of fresh air is made to circulate through the room. In the basement below the larger theatres is a smaller one, the general arrangements of which correspond to the description already given. This is utilized by the department of medicine, the two larger serving the requirements of the departments of surgery, pathology, and bacteriology.

#### Pharmacology

The department of pharmacology occupies most of one side of the ground and first floor. It comprises a lecture theatre additional to those already described with separate entrance for students from the main corridor, a practical laboratory in which a feature is the up-to-date draught cupboard, private laboratory for the professor, several laboratories, workshop, store rooms and side rooms. The laboratories are splendidly equipped and contain the latest kinds of kymographs, pumps for artificial respiration and the other necessary mechanical devices. Power is supplied from electric motors by means of belting to the main driving shafts fitted in each room. The brackets which carry the main driving shafts also convey the electric mains for lighting gas and water pipes, from which supply points are arranged at frequent intervals. A room is set aside for an electro-cardiograph. Professor J. W. C. Cunn, who is in charge of the pharmacological unit, is the curator for the building.

#### Bacteriology

The department of bacteriology is on the other side of the ground and first floors. It comprises retiring rooms and offices for the professor and his assistants, a private laboratory for the professor, a routine laboratory in which the clinical work of the general hospital will be carried on, vaccine preparation and media rooms and a very large practical laboratory for students. This latter is perhaps the feature of the department, and is equipped in almost sumptuous fashion. It contains four rows of work benches, running lengthways, divided into spaces on both sides of the bench allotted to each student. Each space is fitted with microscope, illuminating lantern, rack for reagents and water tap. Suitable provision is made at one end of the laboratory for lecture purposes. The department in addition, contains a mixing room, and has its own self-contained refrigerating plant situated in the basement, by means of which the various cool chambers are supplied.

#### Surgery

The surgical unit situated in the rearmost portion of the left wing of the building on the first floor is ideally fitted and designed for its purpose. The rooms set aside for operative and experimental surgery are lined throughout with white glazed tiles. The former—the larger apartment of the two—contains four operating tables, the latter two. Each table is lighted by a cluster of lamps arranged under one shade working on an adjustable ball and socket joint. Very complete provision is made for cleansing purpose by means of water supply taps and sinks. The rooms would put to shame the operating theatres of any modern hospital. Further accommodation consists of a professor's room, a private laboratory, specimen rooms and a dark room fitted for the most up-to-date method of colour photography.

#### Medicine

The department of medicine occupies a series of smaller rooms in the basement adjoining the lowermost lecture

theatre. There is provided private accommodation for the professor and his assistant, a dark room for photographic purposes, an electro-cardiograph room, and a laboratory for experimental medicine. In this section, too, there is a room intended for the use of the lecturer in public health, as well as a larger apartment to be utilized as a museum for the department of forensic medicine.

#### Pathology

Perhaps the most interesting of all the departments is that occupied by the professor of pathology, which takes up the whole of the first floor and part of the basement in the right wing connected by a covered way with the mortuary and post-mortem rooms which form a separate single storied block detached from the main building. In addition to the rooms set aside for the professor and his staff there is a spacious preparation room where specimens will be received and prepared for examination. The students' practical laboratory, like that in the department of bacteriology, is a really magnificent example of what such a laboratory should be and its equipment is of the finest and most complete description. Another feature of this department is the record room where the facilities for storing and indexing of pathological slides have been designed by a master mind. Below each slide filing cabinet is a series of drawers designed to hold the clinical history of the case from which each specimen is derived, by this means it will be possible to study the section of a diseased organ in conjunction with the medical history of the case. The mortuary block may justly be described as the "show section" of the new medical school. It would indeed be difficult to find in any similar institution a post-mortem room and adjuncts so beautifully designed and fitted for the peculiar local needs of a teaching hospital. In the post-mortem room the tables and walls are of pure white enamel while the arrangements for ventilation and cleansing excite the admiration of even the casual observer. A special feature however is the refrigerating plant, which provides the cold storage necessary to preserve cadavers in a climate so warm and moist as that of the Cape peninsula. It is capable of effectively chilling ten large vaults that open on to a corridor leading to the post-mortem room. Each vault has storage for five bodies and has a special door at the back which permits of a body being taken into a small waiting and viewing room, where friends and relatives can see it in private. In connection with the mortuary is a chapel of dignified design with a separate outside entrance and ante rooms. These rooms are so arranged that Europeans and non-Europeans are kept apart, beside having their use in case of denominations with special rites such as the Moslems. In keeping in mind the small but important details the architect has shown his comprehensive grasp of a scheme which provides such a beautifully designed mortuary unit. This unit will not be utilized until after the completion of the new general hospital.

#### Students' Common Rooms

In conclusion mention should be made of the ample accommodation for students in both sexes in the shape of comfortable common rooms. These are fitted with lockers, keys for which are lent to students on payment of a small deposit. The common rooms are situated in the basement, where too, there is a tea room. Lavatory accommodation throughout the building is more than ample both for staff and students. Protection against fire is adequately provided by the installation at all strategic points of hydrants fitted with pressure gauges indicating the lead of water available. The roof of the building is of tiles and the woodwork throughout of seasoned teak. The furniture in the majority of the rooms is in the characteristic South African style and made from stockwood. This description would be incomplete if it omitted to mention the large modern animal house erected on the grounds where the animals used for inoculation and the necessary experimental work are housed and cared for. Here again scrupulous cleanliness is the keynote and the facilities provided for that purpose are admirable.

## TREATMENT OF INDUSTRIAL RHEUMATISM IN GERMANY

[FROM A CORRESPONDENT]

By invitation from the German Ministry of Health a number of British medical men and twenty representatives of various industrial organizations attended recently the inauguration of a German Committee on Industrial Rheumatism in Berlin. The meeting, under the chairmanship of Professor Dietrich was held in the clinic of Professor Bier, many papers and demonstrations were given, and a general policy was decided upon. Later a few British and Dutch physicians were the guests of the German Spa Federation (Allgemeiner Deutscher Bäder-Verband) at certain health resorts, that they might see on the spot what is being done for the insured patient since the war.

The British party was under the leadership of Dr R. Fortescue Fox, chairman of the Rheumatism Committee of the International Society of Medical Hydrology, which recently met the representatives of the English approved societies to discuss the possibility of establishing a clinic in London on the lines of those already existent in such centres as Berlin, Dresden, Hamburg, and Archen, for the treatment of insured patients. In former times the Krankenkassen (approved societies) had relied for the treatment of their chronic rheumatic patients on contracts with the various spas, of which there are well over a hundred in the country. Of late years, however, the number of these patients, and the expense entailed by sending them to the resorts, have increased so much that clinics were established at various places—often in connexion with a general hospital or university bond, where balneological and physico-therapeutic treatment could be obtained for their members in the town at a much lower cost. For in-patient treatment several large hospitals have been established, notably at Archen, which are said to provide sufficient accommodation for all needs. The patient whose invalidity lasts more than twenty-six weeks, however, is still given the opportunity of obtaining a "cure" at a spa, if the physician in charge of the case thinks that this offers a reasonable chance of alleviating the symptoms sufficiently to raise him from the category of permanent disability. He is then sent for a minimum period of three weeks—which may be extended to a maximum of six weeks—to one of the spas, where he is banded at a low cost either by contract with the small hotels or, in many places, in a home run by the society for this purpose, the employers also contributing.

Sickness insurance appears to be much more far-reaching in Germany, and every grade of the Civil Service (which apparently includes most people) is catered for at some or other of the spas. At Bad Elster, for instance, which is a State spa, there are homes for the workman, the clerk (and family), hospital nurses, State officials of "middle grade," army N.C.O.'s and officers, there is also a home for children. It is held to be important in this respect to consider the social customs of these various grades, and not to emphasize unduly the contrast between their usual surroundings and their spa environment. The patients are supposed to be under rigid medical discipline whilst undergoing the cure, but this seems to vary immensely as the grade of home.

### TOWN CLINICS Hamburg

The Brinbeck Hospital, completed in 1913, contains nearly 2,000 beds, has a department for balneological treatment and physiotherapy to which is attached 200 beds, under the charge of Professor Plate. The great majority of the patients attending are rheumatic subjects, although other cases for which this type of treatment is suitable are referred from other parts of the hospital. The plans for this department were drawn up by a committee, under Professor Pfeiffer, consisting of physicians, surgeons, an orthopaedic surgeon, and an engineer in consultation with the architect. Original work appears to be carried out here in connexion with the treatment of the chronic rheumatic diseases, and the duration of sciatica, in particular, seems to have been reduced by means of Professor Plate's system of intensive treatment. It is strongly held at this centre that these diseases are largely occupational, and a cinema film was shown to corroborate this

there is, therefore, an advisory committee appointed to consider each particular patient on discharge, with a view to discussing the necessity for either modifying or changing his occupation. The insurance companies state that, in their opinion, this has reduced their total sickness payments of late years.

### Berlin

Two clinics were inspected in Berlin, the larger one being a special department of the great Vinchow Hospital. It is under the charge of Dr Laquei, and more than 200 patients are treated daily by the various douches, sprays, water baths, sand baths, mud baths, violet ray baths, vapour and steam baths, hot air baths, and "primal" baths with which the department is amply supplied. There is also an enormous 'Zander' gymnasium, where the patients undergo the vigorous passive movements which characterize that system. The dozen or so unselected patients who were questioned seemed to have derived—from their own account—very considerable benefit from treatment, the duration of which had varied from four to twelve weeks, since all the treatment in this clinic is ambulatory, its duration, so long as my prospect of benefit remains, is not limited, as it is at the spas.

The other clinic (Victoriastrasse) is run entirely by the approved societies for their members, and was founded just before the inflation of the mark. The Government, however, later repaid all their investments in the stabilized currency, and the result is that these clinics are the most lavishly equipped institutions in Germany. Patients can be recommended by any general practitioner since there is no "panel," the insured person having the right to consult any doctor who has expressed his willingness to see this type of patient. If the recommendation is accepted the patient gets five treatments and, after seeing the director, returns to his doctor, who can order continuation treatment if he considers it necessary.

These institutions are mostly staffed by whole-time medical officers and assistants under a medical director, and are open all day and until late at night, for the convenience of patients who can only reach them then.

### Dresden

Saxony is the most strongly socialist of the German States, and considers itself very progressive. Certainly the 'Ostbathenhaus' of Dresden is one of the most palatial modern buildings in the city. It comprises an administrative block and large out-patient departments for the various types of treatment, a feature being the provision of a tiny wooden cubicle for each patient, in which he can undress. The balneological department is a single enormous room in which are some fifteen or twenty baths for the provision of every treatment of this kind. This would probably not be considered a satisfactory arrangement in England, but makes for economy in the number of assistants required, whilst the physician in charge can more easily exercise a general supervision. A large rest room adjoins this department, every patient lying down for half an hour after treatment. It appeared that the chief superintendent was not a medical man, a fact which, it is said, makes for continual friction, and since every case sent up by outside doctors is not, therefore, seen on arrival, the therapeutic facilities of the place are occasionally abused.

In addition to balneology there are departments for massage, Swedish gymnastics and Zander treatment heat and light of all kinds, and electrical treatment, including high frequency for the hand. There is also an advisory bureau for young men and women about to marry, which is advertised locally by means of rather lurid posters designed to point out the dangers of not consulting this centre. As the result of pressure from below the socialist authorities have included practitioners of the popular 'Nature Cure' cult (Naturheilkunde) among their 'panel' doctors, a state of affairs prevailing only in Saxony, and against which the profession are apparently powerless, especially since the doctors' 'strike' some years ago, which revealed the fact that the "blackleg" was not a monopoly of the proletariat.

### Wiesbaden

Wiesbaden, although a fashionable watering place, takes also a considerable number of insured patients, under a contract, and the recently opened Städtischen Forschungsanstalt, which is both a research institute and hospital, accommodates about a hundred in patients, who are thoroughly investigated both bacteriologically and biochemically under the supervision of the director, Dr Hupfender. The building was once a hotel, and has on the premises a warm saline spring, with a Roman tablet extolling its healing properties. Original work on the action of waters on the yeasts and ferments is being carried out in the excellently equipped laboratories, and it is interesting in this connexion to note that research is being supported by the

approved societies in most of their hospitals, though to a varying extent. Patients can be sent here for a three weeks' cure, which is felt by the staff to be too short but may be extended to six weeks, if no other claim has been made during the year by the patient. If no improvement is noticeable after this period the patient is graded by the hospital medical board, and can then go on to permanent sickness benefit. Both lower and middle class patients are treated here, but no distinction is made between them, since no room has more than two beds. The hospital is, in addition, well equipped to give other forms of treatment.

#### Mann (Mannere)

The clinic inaugurated by Dr. Frank in this city more than twenty-five years ago has been the pattern for most of the clinics which have been described above, and from this point of view is well worth a visit, since even to-day there is said to be no essential point of design which it is felt could be improved upon. Only a certain proportion of the cases treated here are not by the approved societies, the rest being private patients, who are graded according to the amount they feel inclined to pay into four classes. The director exercises a general supervision, but himself treats only those cases specifically referred to him.

#### Aachen

Aachen (Aix la Chapelle) lies in a valley some six kilometres only from the frontiers of both Belgium and Holland. Its natural sulphur springs are from the medical point of view its greatest asset; they are amongst the hottest in Europe, and since Poman times have been frequented for the treatment of rheumatism and skin diseases, and when combined with inunction have long been used for patients suffering with the later manifestations of syphilis, particularly those intolerant of arsenic. Early cases are not considered suitable.

The Landesbad Hospital, founded in 1912 by the insurance organization of the Rhine province, is probably one of the best equipped institutions in Europe, and can accommodate nearly 400 in-patients, about a third of whom are women. Dr. Krebs is the director, and the medical staff is on a whole time basis. No out-patient department is attached to the hospital, since the patients are sent direct by a medical board at Düsseldorf, which accepts also members of other friendly societies at a slightly increased rate of payment. The patient's third-class railway fare is paid if he has to come from more than a certain distance. The inmates are only allowed out of the building once a week, but a spacious garden is provided for them, as also frequent lectures, outings and social evenings. A research department was opened during this summer under the general control of the Faculty of Medicine of Düsseldorf, and post-graduate lectures and courses are to be given during the winter.

#### Stassfurt

The spa treatment of chronic rheumatism, although in use since the Roman era, has until recently been regarded with a certain amount of suspicion by the medical profession, owing in all probability to the largely empirical nature of the methods employed. This is presumably still the attitude of a minority of the profession in Great Britain. In Germany the subject was taken up from a scientific point of view at the beginning of the present century by men appointed by the universities and is the result of their inquiries, the approved friendly societies decided to include spa treatment amongst their additional benefits—largely also, it is said, owing to the alarming increase in their dental payments for chronic arthritides. The societies in their recent reports state that they have arrived at the conclusion that this policy has paid in view of the fact that one-sixth of their total invalidity results from this cause, a figure which, according to the Ministry of Health's recent report, also holds good in England. They further point out that the provision made for tuberculous subjects has always in the past been much more adequate, although the rheumatic patient predominates in the proportion of 8 to 1 (Zimmer).

A few selected spas of differing characteristics were visited by the British and Dutch physicians, a brief description of them follows in the order in which they were visited.

*Odenkirk* which rather grandiloquently styles itself the city without steps, is a small town about one hour by train from Hannover. It is picturesquely situated in a valley between the wooded slopes of the Teutoburger Wald. It boasts five saline springs, heavily charged with carbonic acid gas, the

chief indications for treatment being, therefore, rheumatism and nervous diseases, but heart disease is also treated on lines practically identical with those used at Nauheim. As a spa it takes itself seriously, and provides little in the way of entertainment other than an excellent band and a Kurtheatre. There are also the sedative delights incidental to fine buildings, and a well laid out Kurpark. The results, claimed in rheumatic cases, are good, although a repetition of the cure is advised even when apparently successful. At the Auguste Victoria Children's Home nearby twenty-five post-rheumatic cardiac cases are treated for periods of four weeks all the year round on Nauheim lines, the earliest acid bath being used largely. The treatment aimed at in the nervous cases is largely sedative and is said to alleviate spasm. The waters are given both externally and internally by the latter method apparently with great frequency.

*Eisen* is a two-hour journey by motor from Odenkirk. The road lies through the picturesque gap in the wood-clad mountains—the Porta Westphalica—out of Westphalia and into the true ex-principality of Schaumburg-Lippe. The ex-prince who is still wealthy enough to command the respect of the local democrats has employed his leisure to build a colossal hotel which is advertised as a *Kaiserhof*. A *Hofstille* of quiet refinement and has partly furnished it from his Schloss. Adjoining this is a model bath house in which the potent cold sulphur water of which there is a most unusual amount in the vicinity can be taken in any form—both drunk, or inhaled the last being given by means of the recently invented Italian method of using a dry vapour. Mud baths are also much used. For those who require less magnificent quarters there are two other large hotels, all three being run in conjunction with one another, and sharing the very delightful Kurpark. There seemed to be no insured patients in Eisen.

*Bad Nenndorf* is said to owe its origin as a spa to the fact that Jerome Bonaparte was cured of his rheumatism after bathing in its four hot sulphur springs; it is largely owned by the State of Prussia and is now used almost entirely for the treatment of insured patients, the establishment being open all the year round. For the most part the accommodation is unpretentious, and many are boarded out in the town at an average cost of a mark a day, the cost of the cure, which lasts here four weeks is extra. The expense of this is calculated on an average basis of twenty marks per bath at a cost price of 4 marks each, but these baths may, if the patient wishes to economize, be used on three occasions at no extra cost; this is not, however, advised, since the therapeutic potency is said to suffer by reheating. The natural water here is said to be of double efficiency in the treatment of the rheumatic since in addition to its strong sulphur content it contains 6 per cent of bromine. It is for this reason also much used in the treatment of chronic respiratory disorders, chiefly by inhalation and vaporization and of skin complaint. For the casual visitor Nenndorf is not always a pleasant place, since the sulphureous fumes penetrate to all the beds of the hotel and strong men have been known to curl their lips at the account. Drawbacks of this nature are however thought to be more than made up by the picturesque native costumes worn by the peasants on Sundays and holidays, and by the hospitality of the residents.

*Pyrmont* the next spa to be visited is reached by a road which passes through the quaint little town of Hameln on the river Weser, the scene of the famous Pied Piper legend of the thirteenth century. This is amply commemorated there by a tablet in the church by the piped piper's house in the main street and by scores of rats of all sizes made in glazed brown bread with bead eyes which are pressed upon one in shops of all sorts. There is also a table commemorating the reputed discoverer of morphine who lived in this town. Pyrmont which stands about 450 feet above sea level in a valley well protected from north and north-east winds was known as a spa in Poman times when sterility cures seem to have been practised and even now it is known principally as a woman's spa. The water contains a high percentage of sodium chloride and that from the chief spring in addition iron and carbon dioxide. Mud is obtained by light railway from a large lake nearby and is said to be of exceptional potency. Pyrmonter applies its water in bottles by contract to some of the city clinics for insured patients, but is rapidly becoming one of the most popular watering places in Germany, and consequently not very much is done for such patients on the spot. The general opinion throughout Germany appears to be that the presence of insured patients in any number has a detrimental effect on the spa from the moral point of view, by keeping away many of the wealthier classes who would otherwise patronize it accordingly the trend of policy is to devote the smaller spas to the cure and more of the service of the

Krankenanstalt which keeps the larger and better known almost exclusively for the use of the paying patient. Exceptions to this policy are made in many places, such as Wiesbaden, where considerable numbers of insured patients are treated in

their own institutions, and do not, consequently, take much part in the life of the place.

*Bad Elster* is a small State owned spa, situated amidst beautiful forest scenery 1,000 feet above the sea. It is only twenty minutes from the Czechoslovakian frontier, and is thus brought into competition with the spas over the border in the neighbourhood of Karlsbad. It is consequently the cheapest of the German resorts. Its chief additional medical assets are a bracing but uniform climate, twelve alkaline saline springs—some of which also contain carbon dioxide (Marienquelle)—and two lady doctors. Mud (peat), iron, and pine needle baths are used extensively, heart disease used to be treated here more than is now done, and an elaborate system of graduated walks exists up the neighbouring hillsides for the after treatment of these cases. There is also an open air theatre, restaurant, and dancing place. As has been mentioned previously, a very large number of insured patients are treated here annually, and homes exist for their accommodation, the average cost for a patient whilst living in a home and taking the cure is 3.50 marks a day, with a 20 to 100 per cent reduction in the cost of his treatment and doctors' fees. The most palatial of these homes is for clerks and their families, but appears originally to have been established under a private bequest. The spa is not, according to Herr Etienne, the director, primarily run as a business proposition, only a small margin of profit being aimed at, since any renovations or building operations which may become necessary are undertaken by the State, which, in return, has the right to send 200 patients for free treatment and 250 at half price every year. For his services the doctor, who is selected by the patient, receives 10 marks, and is required to see him twice. The cost to the spa is worked out on a basis per patient of twelve peat baths and six carbon dioxide baths, the former being by far the more expensive item.

Apart from the insured patient, Elster is also patronized to a considerable extent by the middle classes, who were particularly hard hit financially during the crisis in 1923, and a certain number of these patients are also able to get a reduction in their fees for the cure. This number is, however, limited, although not rigidly. No mention of Elster would be complete without reference to Dr Kohler's magnificent sanatorium, which is equipped completely for the balneological and physical treatment of rheumatics, or to the tuberculous children's home, which he runs by means of voluntary contributions—amongst others, from the English "Save the Children Fund"—and which is a model for other homes of the sort.

From what has been said it will be evident that a great deal is being done in Germany for the insured rheumatic patient, and the fact that it has now been done for some years would appear to show that the approved societies find that financially it "pays." Representatives of these societies were interviewed, and although, as they say, actual statistics on such a point are unsatisfactory, they were agreed that this was so.

With regard to the position of medical men under this scheme there seems to be less unanimity, they are but poorly represented on all the insurance boards, and in the matter of clinics also they do not seem to have been given due consideration, in all cases the chief bone of contention is undoubtedly that of the increasing expenditure, which is laid by the societies entirely at the door of the doctors. From 1884 to 1914 sickness benefit payment had increased ninefold, according to the reports, what they do not appear to have noticed, however, is that during that same period the administrative expenses had increased fourteenfold (Finkenrath).

There is in Germany no category for "additional benefits," and spa and allied treatments accordingly come under the "general treatment" heading, as do all new or improved methods and drugs, it is reasonable, therefore, to suppose that an increase in the sick payments was inevitable when these methods were sanctioned. The efforts made by the societies to check this increase appear, however, to fall almost entirely upon the medical profession, to their eternal tribulation.

Whether or not the establishment of some similar scheme in England is possible as has been recently suggested, it is outside the province of this article to discuss, but the advice proffered by a distinguished German medical man—to the effect that if a move be made, let it originate from the medical profession and not the societies—would appear salutary in view of the position of affairs in that country.

## THE BERNE INTERNATIONAL CONFERENCE ON GOITRE

The International Conference on Goitre held in Berne on August 24th, 25th, and 26th drew about 120 experts from sixteen different countries. One of the objects of this conference was to promote, among experts representing every phase of the subject, formal and informal discussions on goitre, and the extent of the ground covered may be partly gauged from the fact that eight hours a day were spent at the formal meetings alone. The programme of the conference provided for an opening speech on the frequency of goitre in the different countries by the president, Dr H. Carrière. Papers on the pathological anatomy of goitre were read by Dr Aschoff of Freiburg and Professor Wegelin of Berne. In the place of Dr Marine of New York, a paper was read by Dr Graham of New York on this subject. He also dealt with the relationship in the United States between goitre, on the one hand, and cretinism and deaf-mutism, on the other. Professor Huguenin of Berne gave an account of goitre among domestic animals in Switzerland, and Dr Holst of Oslo drew attention to the remarkable frequency of this disease in the coastal districts of Norway. The pathological physiology of goitre was discussed by Professor de Quervain of Berne and Dr Breitner of Vienna. Dr Plummer of the United States was unfortunately prevented from attending this meeting. The etiology and epidemiology of endemic goitre were allotted to four introductory speakers, Professor Bernard of Lyons, Lieut-Colonel Robert McCarrison of the Pasteur Institute, South India (whose paper was read by Sir James Berry), Professor Galli-Vallerio of Lausanne, and Dr Birchler of Aarau. In the discussion which followed attention was drawn to the influence on the provocation of goitre of such factors as the contamination of food and drinking water supplies.

The introductory speakers on the prophylaxis of endemic goitre were Professor Wagner von Jauregg of Vienna, Dr Mugger de Sondrio of Italy, and Professor Silberschmidt of Zurich. The Swiss authorities and the foreign visitors drew attention to the value of the energetic prophylactic measures adopted in certain Swiss cantons, the provision of iodized salt for wholesale consumption in small quantities being particularly praised. Professor Nicolaysen and Dr Lunde suggested that something could be done to reduce goitre by a diet of sea fish whose iodine content is exceptionally high. The benefits of iodine prophylaxis were, however, queried by some speakers.

The president's proposal that this conference should be followed by another on similar lines received general acclaim, the success of the conference may, indeed, be measured to a certain extent by the general expression of a desire to see it soon repeated. The work of its secretary, Dr Stiner, was greatly appreciated. It should be added that the goitre exhibition organized in connexion with the conference proved a most attractive side-show. The following are some of the points made by Colonel McCarrison.

### *The Etiology and Epidemiology of Endemic Goitre*

Colonel McCarrison insisted that the constellation of causes which gives rise to goitre is not always the same, nor is the character of the disease identical in different parts of the world. Of the many theories professing to account for the origin of this disease, two have survived. The first is the iodine deficiency theory, the second as the infectious or toxic theory, which attributes goitre to some unknown pathogenic organism or to its products. Colonel McCarrison has come to believe that the truth lies in a judicious blend of both. In Himalayan India there is no evidence that the incidence of the disease is in inverse ratio to the iodine content of the soil. The water supply of two places some miles apart may be the same, yet goitre is present in one and not in the other. Drinking water containing 300 parts of iodine per 100 billion parts of water has not prevented the occurrence of the disease in endemic form in the presence of a high degree of bacteriological impurity of the water, the substitution of a bacteriologically pure for a bacteriologically impure water has caused the rapid and complete disappearance of

the disease from a place in which it had been endemic for seventy years, although the new water supply contained less iodine than the old. Iodine-containing salts appear, however, to have an influence in preventing this type of endemic goitre.

Colonel McCarrison recently obtained a deteriorated and bacteria laden rice from a notorious locality in Burma which caused large hyperplastic goitres in 12.5 per cent of birds fed exclusively upon it—a result suggesting that some positive goitre-producing agency, probably bacterial, was present in this rice. Its iodine content did not differ from that of other rices. In 1927 he found that, while a minority of pigeons developed large hyperplastic goitres when fed exclusively on an iodine-poor diet of American white flour the majority did not. The occurrence of goitre in the minority could not, therefore be attributed solely to iodine deficiency, but to the action of some positive agency peculiar to the affected birds. In iodine poor localities goitres may develop spontaneously in well fed animals confined in dirty cages, only the most meticulous cleanliness prevents goitre in laboratory animals in such localities. It can also be prevented by increasing the consumption of iodine or cod liver oil. Chlorine acts in a similar way but with less certainty. Iodine antiseptics—thymol, salol, B-naphthol and *B. bulgaricus*—given to the subjects of goitre cure it in many cases, notably recent cases without any change being made in habit of life, place of residence or food.

After giving an account of his experimental production of goitre in goats and rats and the experimental prevention of goitre in man, Colonel McCarrison concluded that the essential cause of the type of goitre with which he was dealing is a positive toxic agent derived from the gastro-intestinal tract. This agent may or may not itself cause chronic hypertrophic goitre in the presence of a sufficiency of iodine, nor may an insufficiency of iodine cause the disease in the absence of gastro-intestinal infection. When both factors are present the conditions for the development of this type of goitre are at their optimum. Hence his recommendations for the prevention of this disease and its sequelae: (1) the perfecting of sanitation, (2) the provision of pure and protected water supplies, (3) efficient personal hygiene and drainage of the gastro-intestinal tract, and (4) the use of a well balanced food containing a sufficiency of iodine in a natural state.

## THE VETERINARY CONGRESS

The annual congress of the National Veterinary Medical Association of Great Britain and Ireland has been held this week at Torquay, under the presidency of Mr. GEORGE WOOLDRIDGE, professor of medicine at the Royal Veterinary College, London. Among the numerous papers on general veterinary subjects two submitted to the Section of Veterinary State Medicine are of special interest to medical men.

### Meat Inspection

Lieut.-Colonel T. O. Young, in discussing the "Veterinary surgeon in relation to meat inspection" stated that an ideal system of food inspection should include slaughter of all animals in public abattoirs, ante-mortem and post-mortem inspection by trained officer of all animals intended for human food, and inspection of all meat products and food factories. This system was in practice in many countries, including those from which this country obtains much of its food supplies, but no serious attempt had yet been made to adopt a similar system in England. Here meat inspection was only one of the numerous duties of a sanitary officer instead of being a special duty. Regulations existed but their great weakness in practice was the lack of uniformity. One difficulty connected with a satisfactory system of inspection was the number of private slaughterhouses existing in England (about 20,000) this made regular and thorough inspection impossible. The position was different in Scotland, where 90 per cent of the home-produced meat was prepared in public abattoirs. The English Departmental Committee which inspired the Public Health (Meat) Regulations of 1924 recognized the necessity of reducing the number of slaughterhouses. Both

it and the Scottish Committee also considered the subject of the qualification of meat inspectors. The latter decided that only medical or veterinary officers should be in charge of meat inspection with lay assistants where necessary, to act as 'detention officers'. The English Committee was less definite and admitted the employment of non-professional officers, owing to the prohibitive cost of employing an "ideal staff". In England (but not in Scotland) veterinary officers have no official power to seize unsound food, the statutory right at present rests in the medical officer of health, the sanitary inspector or inspector of nuisances. This was an extraordinary state of affairs, and should be remedied. Dr. Leighton regarded food inspection as being supervised by the medical officer of health, who mainly occupied in administration and matters of policy, would act only in the nature of a consultant, the inspection was carried out by the veterinary surgeon, who would do the actual inspection of meat and milk.

Lieut. Colonel Young said that no satisfactory system could be evolved until in every city and urban district veterinary officers were appointed in the public health departments. These duties would include: (1) inspection of all diseases under the Diseases of Animals Acts, (2) care of all horses owned by the local authority, (3) inspection of cows and cow sheds under the Dairies and Tuberculosis Orders, and (4) inspection of all animals slaughtered for food. They would probably need assistant veterinary officers or thoroughly trained assistant lay inspectors or both.

### Diseases of the Cow in Relation to Milk Legislation

Mr. BRENNAN DE VINCE, in opening a discussion on this subject said that the cow filled a very important place in public health legislation being attacked by many specific diseases, not a few of which were common to the cow and man. The most important and serious bovine disease in Britain was tuberculosis. The prevention of the infection of man was to a certain extent provided for in the Milk and Dairies Act which prohibited the sale of milk from a cow affected with tuberculosis of the udder. Cows not in milk but affected with tuberculosis of the udder were dealt with under the Tuberculosis Order, but as this only applied to advanced cases no great decrease in the number of diseased animals could be expected. In any septic condition of the uterus discharge might be transferred to the milk and any diseased condition of the udder or teats might render the milk harmful. In streptococcal mastitis the milk might cause sore throat in man and in actinomycosis a not very common condition in the udder, the infection might be carried to man by the milk. Although there were very few cases on record of the conveyance of anthrax infection to man by milk, the use of milk from infected animal should be prohibited. Foot-and-mouth disease was easily conveyed through milk, although in affected animals the yield was small.

### The Application of Electrotherapy to Domesticated Animals

Lieut.-Colonel MONTGOMERY PERCY said that high frequency treatment applied for from five to even minutes daily had given most gratifying results in cases of paralysis from various causes and had a wonderfully bracing effect on the whole system. It was a good stimulant to the skin and the growth of hair and many cases of rheumatism were amenable to it. Fulguration had given good results in treating the small unpedunculated fibrous growths so common on the skin of many dogs. Ionic medication was useful so far as it could be applied in veterinary medicine for conditions similar to those treated in this way in man. Ultra-violet radiation gave excellent results in rickets, especially in the heavy breeds of dogs. Its effects were increased by the exhibition of cod-liver oil. Good results followed this treatment in eczema and indolent wounds and ulcers often unresponsive to other forms of treatment, readily yielded to this. He concluded by discussing the value of x-rays as a diagnostic agent—especially before operations—in dogs and cats.

Other papers dealt with diseases of the udder and teats, other than mastitis, the clinical aspects of ringworm and eczema in the dog, lightning and electric shock in animals, and intestinal parasitism.

SATURDAY, SEPTEMBER 17TH, 1927

## THE PUBLIC HEALTH A STOCK-TAKING

MEDICAL practice, that hilly-burly of problems and emergencies, affords but little opportunity for the 'quiet calm deliberation' which, as W. S. Gilbert has told us, "disentangles every knot." Scant time is available for a survey of positions which have been won in the campaign against disease, or a critical study of the bewildering profusion of new methods of medical treatment. In these circumstances Sir George Newman's annual report on the state of the public health,<sup>1</sup> of which our concluding notice appears this week at page 499, is most welcome. We commend it in particular to the busy practitioner, who can hardly fail to draw from its pages both encouragement and practical help in his own work. The summary, with which the report ends, can be read in a very short time, and yet it gives a remarkably comprehensive sketch of the principles underlying the maintenance and restoration to health, both individual and collective.

"The function of the sanitary reformer is to reduce every reducible known cause of disease to its least possible degree of destructiveness." So wrote John Simon nearly seventy years ago in one of his masterly papers on the sanitary state of the people of England. The condition then was deplorable, and the ineffectiveness of public authorities a disgrace. Simon saw clearly enough that reform would be a long and hard business, uphill all the way. "It is indeed only by very gradual increase," he said, "that legislation and government can succeed in giving to human life the same security against the infliction of preventable disease as against the infliction of wilful violence, and millions may have died before this public carefulness for individual safety can have become co-extensive with even the present certainties of preventive medicine. But growing knowledge will bear its fruit." Growing knowledge has indeed borne fruit in this country since 1858, and a national sanitary conscience has grown up, so that it is possible for Simon's lineal successor, the Chief Medical Officer of the Ministry of Health, to write in 1927 "I suppose it is correct to say that never before in the history of this country has so much been attempted by the State on behalf of the health of the people as now."

The science and art of Preventive Medicine is extending in almost all directions, knowledge of it is becoming more applicable and effective, and public opinion is supporting the cultivation of health and fitness in the individual. These changes indicate an immense awakening and a wider use of the improved environment and health facilities which the State has provided. Much disease and impairment remain, but evidence and experience suggest that we are on the high road to their amelioration.

The attainment of this happier position is admittedly due to the extension of preventive and curative medicine, and to their better co-ordination, yet no one will deny that much remains to be done. A wider outlook is essential, both on the part of the State and municipal official, who must co-operate freely with all

who labour in the interests of the health of the community, and also of the general practitioner, who is being increasingly called upon to recognize that his duties embrace the work of communal as well as of individual medicine. Each appearance of the Annual Report of the Chief Medical Officer enables the working practitioner to take stock of the progress of the whole health movement, by using this recurring opportunity his hands will be strengthened, and he will be armed against those doubts and attacks which he inevitably encounters from time to time. For instance, the arguments and assertions of those who would deny to the community the benefit of vaccination against small-pox, without offering anything in its place, are effectively countered in the two pages devoted to a summary of the reasons for a belief in the value of this practice. Again, the shallow criticism too often directed against medical scientists—"Who shall show us any good?"—receives in the report a convincing answer. The extent and nature of the benefit of national health insurance to the community is clearly brought out. Many other instances of important subjects, effectively yet briefly treated, will be found.

This report, then, deserves close study, both by those who welcome stimulus for thought and by the many who need concentrated practical information. The yoking of statistical science to the everyday problems of life is no mean achievement, and when, as here, a judicial attitude is preserved, and the results are set out with philosophical deliberation, the conclusions are worthy of very careful consideration. The far-reaching influence of the British Broadcasting Corporation is used one evening lately to advertise to women the practical value of this balance sheet of human health, it is obvious, therefore, that it must receive the special attention of the medical profession, whose members may otherwise find themselves in the awkward position of being less well informed, on some points of detail or even of principle, than those whom it is their duty to instruct in the conditions of health. Finally, the considered optimism which characterizes the report as a whole may well bring encouragement to the great body of general medical practitioners, many of whom, in the stress of their daily round, have little time to reflect on the large share they themselves take in promoting the happiness and well being of their fellow men.

## BIOMETRICAL INVESTIGATION OF DISEASE

A NOTEWORTHY development at the Johns Hopkins Hospital, Baltimore, is the utilization of its elaborate clinical notes by the application of modern statistical methods under the inspiration of Professor Raymond Pearl, who is head of the department of biometry and vital statistics in the School of Hygiene and Public Health, and of biology in the Medical School of the Johns Hopkins University. In the past the pioneers of biometrical methods were primarily biologists, and between biology and medicine there was a gulf which made sympathy and correlation difficult. Now the sciences of physiology, anthropology, and biometry are being applied to medicine with, it may be anticipated, great advantage to a profession which is both an art and a science. Statistical methods demand a mathematical knowledge rare among medical men, except those whose training or temperament has been on rather exceptional lines. Professor Karl Pearson, who was third wrangler at Cambridge in 1879, is the

<sup>1</sup> On the State of the Public Health. Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1926. H.M. Stationery Office. (Sold 8s. 6d. net.)

founder of the British school, but it is perhaps remarkable that among his pupils few have come from that university.

The twenty-first volume of the *Johns Hopkins Hospital Reports*<sup>1</sup> contains two fasciculi devoted to the elucidation of morbid conditions by biostatistical methods. Four years ago reference was made in these columns (1923 I, 1104) to the first of a series of biometrical studies in pathology, dealing with the quantitative relations of certain viscera in tuberculous—by Raymond Pearl and Agnes Latimer Bacon. Examination of a group of cases in which the morbid lesions were those of tuberculosis led to the conclusion that the heart was relatively small and the spleen large—a different conclusion from that drawn from the study of patients with tuberculosis which was inactive and accompanied by other morbid conditions. These results led to an investigation of the absolute weight of the heart and spleen in tuberculous persons. Utilizing the same material—1341 necropsies showing tuberculosis of some sort, 825 being active and 516 inactive—the authors undertook to elaborate data and to correlate the absolute weights of the heart and spleen with age. These age organ weight tables at once showed it might be expected (1) that the weights of the organs changed with advancing age but (2) that this regressive change was not linear indeed. From it especially in the case of the spleen the absolute weight of the heart was notably larger at each age from birth to an age somewhere between 35 and 55 and then steadily but more gradually got less; this curvilinear form of the regression line is essentially the same at the same age in the two sexes and in whites and negroes whether or not the heart shows pathological lesions. The heart is smaller when tuberculosis alone kills than when other pathological lesions are partly responsible for death. In like manner the regression of the weight of the spleen is progressively greater up to the decade centering at 35 years, and then becomes less; the absolute weight is greater in the negro race than in whites, and there is a tendency for the spleen especially when it does not show any morbid change to be heavier when tuberculosis is the only significant pathological lesion but, contrary to the suggestion made in the earlier paper, comparison with the tables of the weight of the normal spleen shows no evidence that the spleen of patients with tuberculosis is heavier than that of normal non-tuberculous persons.

The other paper which is by Miss Mary Gover is a statistical study by modern methods of the etiology of benign hypertrophy of the prostate and is based on the punch cards each of which contains 156 items or 997 cases examined microscopically at the Johns Hopkins Hospital. The conclusions drawn are interesting but largely of a negative character. There is not sufficient evidence to warrant a definite decision as to hereditary influence. Patients who had had gonorrhoea—33 per cent—formed a group having in early age of onset and operation, possibly due to gonococcal complications for the prostate was smaller than in the other cases so that it may be said that gonorrhoea does not cause hypertrophy. Single men appeared to be not so liable as married men but when they did suffer the prostate was as large as in the married no relation could be shown to exist between the patient's reproductive activity and the size of

the prostate nor did alcoholism seem to exert any influence in this direction, men following sedentary occupations were not more prone to prostatic hypertrophy than those engaged in active physical work. There was no correlation between the systolic blood pressure on admission and the weight of the prostate. It appears that the increasing growth of the prostate with age is not continuous; it occurs mainly between 45 and 75 years of age and both before and after this period is slower. The average age of onset of symptoms was 60.2 and of operation 66.7 years.

#### THE WHITE MAN IN THE TROPICS

For long it was taken for granted that the tropics were necessarily unhealthy for white men and the prevalent sickness and high mortality in hot countries were ascribed to telluric influences inseparable from the climatic conditions. As knowledge of the etiology of tropical diseases increased and practical methods of prevention developed, there followed a swing of the pendulum until nowadays some hold that the climatic conditions of hot places are negligible and that exogenous disease and incorrect diet are the only obstacles to the permanent settlement of white races in the tropics. The question is obviously important, and much interest has been aroused in it by the advocate of a white Australia. Divergent views have been expressed with considerable vigour but without any convincing evidence based on scientific inquiry. Sundstrom, working in Townsville, North Queensland, has approached the problem by studying the various changes which occur in vital processes when men accustomed to temperate climates are transferred for shorter or longer periods to the tropics. Townsville described as the largest tropical community in the world with a pure white population offers excellent opportunities for such inquiry and the likelihood of physiological modifications being confused with changes due to disease is less there than in most other tropical towns for locally acquired malaria and other parasitic affections are uncommon. Various examinations including those of the blood sugar and phosphorus contents, protein metabolism, water regulation and comparisons of the results with the standards in temperate climates, seem to indicate that climatic factors do exert a definite influence calling for human adaptation which may or may not be adequate. This is about as far as Sundstrom is willing to push his conclusions though he regards the adaptation required to meet the altered cooling power of the environment as making demands upon the whole bodily economy, the necessary alterations extending beyond the ordinary heat-regulating mechanism. Some Australian writers have laid stress upon the fact that local insurance companies accept proposals from the residents of North Queensland at the same rates as apply to temperate regions. When the point was raised at a recent meeting of the Institute of Actuaries in London no definite opinion was expressed regarding tropical Australia but the general view seemed to be that on a life-table basis an extra premium was necessary in any part of the tropics. Insurance tariffs, however, represent the business policies of the companies concerned and into this question there will enter other factors besides the mathematical expectation of life. Professor H. Pricley, to whose investigations at the Institute of Tropical Diseases at Townsville we have previously referred (*Journal* 1922 vol. II p. 253) when addressing the Pan-Pacific Congress in Australia in 1923 expressed the opinion that physical health need not suffer but he made reservations as to the effect of hot climates upon mental health. The diversity of views upon this aspect of the subject was illustrated last year in the correspondence which followed the publication of a letter by the Bishop of Singapore upon

<sup>1</sup> The Johns Hopkins Hospital Reports, Vol. XXI, Fasciculi II & III, Statistical Study of Benign Hypertrophy of the Prostate Gland by Mary Gover. Fasciculus I, *Biometrical Studies in Pathology—III*, The Absolute Weight of the Heart and Spleen in Tuberculous Persons by Raymond Pearl and Agnes Latimer Bacon. Baltimore: The Johns Hopkins Press, 1925 and 1926.

mental irritability and breakdown in the tropics (JOURNAL, 1926, vol 1, p 503) More work upon the lines of that done by Sundstroem is required, but very much fuller data are necessary before such comparisons as he makes can safely be accepted. Meantime, in North Queensland a great experiment is in progress. Several generations may have to pass before conclusive results can be obtained, for the considerations involved are so numerous and so interwoven that the proof of this pudding may well be in the eating rather than in minute analysis of its ingredients.

#### STANDARDIZATION OF ULTRA VIOLET LAMPS

ATTEMPTS to measure and standardize ultra-violet radiation are being made continually, but most of the methods suggested, scientifically sound though they may be, appear too cumbersome for use in practice. In some of the latest work in this field, which has resulted in a chemical method of standardization,<sup>1</sup> it is admitted that some simpler procedure is necessary, and experiments are being continued from that point of view. The method employed in this instance depends upon the photochemical decomposition of oxalic acid in the presence of uranium acetate, which furnishes a measure of the strength of the emitted ultra-violet radiation. It has been used for the testing of carbon arc lamps employed for light treatment at the Birmingham City Sanatorium, and certain interesting comparisons have been made between lamps of different electrode characteristics. Lamps having carbons with a mineralized core were found, on a 30-minute test, to be 2.7 times as strong in ultra-violet action as lamps having two carbons of the ordinary kind, and on a 15-minute test to be 3.3 times as strong. When the upper positive electrode was a carbon with a mineralized core and the lower negative electrode an ordinary carbon, the results on a 30-minute test were 2.9 times, and on a 15-minute test 2.6 times, as strong as with ordinary carbons. With the carbon-tungsten arc a silver lens is interposed for local treatment, and with this lens in position the ultra-violet radiation at 12 in. from the arc was found to be eight times as strong as the radiation at 28 in. (the usual distance between the patient's thorax and the arc) from ordinary carbons. Without this lens the carbon-tungsten arc had about one-third of the strength of ordinary carbons calculated on a 15-minute test. The experimenters (Mr J. E. Moss and Mr A. W. Knapp) found that the mineralized carbons had a tendency to splutter and obviously to vary in emission from minute to minute, the carbon-tungsten arc also spluttered slightly and required occasional adjustment of its electrodes, but ordinary carbons were much more constant. The quantity of ultra-violet radiation reaching a patient depends upon the source of the radiation, the distance and position of the patient in relation to the source, and any interposed material such as lenses or screens. These investigations have established that the intensity of the radiation at any given point is shown by the oxalic acid decomposition test is inversely proportional to the square of the distance of that point from the source of the rays. If, therefore, two patients are exposed to the radiation from the same arc at the distance of one yard and of two yards respectively the former will receive four times as strong a dose as the latter. When the range from the part treated to the naked arc is 18 in. or less, small variations in distance should be avoided or careful allowance should be made for them. If only one carbon arc is used for the treatment of a number of patients simultaneously, the patients should be placed around the circumference of a circle drawn on the floor, the centre of the circle being vertically beneath the arc, but when, as often happens, two arc lamps are used, the

curve joining the points of equal exposure approximates closely to an ellipse. The authors examined one arrangement whereby one of two patients who were supposed to be receiving the same treatment from two carbon arcs was actually receiving one-third more radiation than the other. Some tests have also been made by oxalic acid decomposition on the difference between sunlight and mercury vapour lamps. The radiation at 8 in. from a mercury vapour lamp which had been in use for 100 hours proved to be one and one-third times as strong in ultra-violet as brilliant July sunshine at Bournemouth, at 25 in. the light from the lamp was only about one-eighth of the strength in this respect of bright sunshine. The trouble in all this work seems to be that it is only possible to argue loosely from lamp to lamp or from the output of a particular lamp at one stage to its output at another.

#### CHRONIC INTESTINAL AUTO INFECTION

CHRONIC intestinal auto-infection is defined by Dr P. Desgeorges<sup>2</sup> of Vichy, who has written much on this debatable subject, as the intermittent, transient, or more or less constant passage of comparatively slightly virulent bacteria from the bowel into the circulation, and, though slowly producing widespread changes, very different in its results from those of the cases of undoubted *B. coli* septicaemia. This difference must obviously depend on the size of the dose and the resistance of the body. The author's experimental injection into the veins of a rabbit of one million colon bacilli did not give rise to bacteriæmia, whereas another rabbit injected with fifty millions became acutely ill and gave a positive blood culture. In chronic intestinal auto-infection the number of bacteria in the blood at any one time is so small that blood cultures are sterile, although, as Adams and his co-workers showed in 1899, visceral invasion proves that bacteriæmia occurs. The question must naturally arise in the reader's mind how to distinguish in practice between the more familiar chronic intestinal intoxication, in which the absorption of poisons only is predicted, and the graver chronic intestinal auto-infection. The criterion appears to be provided by the presence of bacteria in the urine, and Dr Desgeorges protests against the view current in France that all women have coli-bacilluria, and that therefore it is unimportant, in all positive cases he has been able to correlate with the presence of bacteriuria symptoms which wax, wane, and diminish in proportion to its degree. Among 25 cases he found the colon bacillus in 69, the enterococcus alone in 10, and in combination with the colon bacillus in 5, in one instance he found both the *B. coli* and *B. paratyphosus*. Often, no doubt, chronic intestinal intoxication and infection are both present, and Dr Desgeorges admits that Sir Arbuthnot Lane and he are very often applying to the same condition different names, but he maintains that the conditions are different. The region of the caecum and ascending colon is regarded as a special site of entrance of the bacteria which reach the circulatory system, the kidneys, and the body generally, not so much by way of the portal vein, as has often been assumed, as by the lymphatics and the thoracic duct. The passage of bacteria to the liver, which is responsible for inflammation of the biliary tract, hypercholesterolaemia and gall stones, is considered to occur through the hepatic artery. Chronic intestinal auto-infection Dr Desgeorges believes to be three or four times commoner in females than in men, on account of constipation, visceroptosis, the sedentary life, and pregnancy. It is hereditary and familial, but rarely congenital. Besides stasis in the caecum and ascending colon, chronic appendicitis, colitis, bites of ova and inflammation impairing the resistance of the colic mucosa,

<sup>1</sup> The Examination of Carbon Arc Lamps By J. Ewart Moss A.I.C., and Arthur W. Knapp, F.I.C. *British Journal of Actinotherapy*, May, 1927.

<sup>2</sup> Desgeorges, P., *Revue de méd.*, Paris, 1927, xlii, 167-183.

are etiologically important. The kidney and the liver which excrete the bacteria are specially prone to suffer from chronic inflammation and disorders of excretion is common, and a form of umbiligo, peculiar in being worse in the recumbent position and so at night, occurs in the absence of any definite renal lesion. The general symptoms are, like those ascribed to intestinal stasis, piteous, especially "the enteroneurotic syndrome which includes the majority of so-called nervous disorders of an indefinite character." Cancer, however, is not mentioned. Treatment is not so easy as diagnosis; surgery has its place when adhesions or chronic appendicitis are responsible, dieting and treatment at a health resort are important, but vaccine therapy is usually disappointing.

#### MEDICINE AND THE FRUIT INDUSTRY

The activities of modern industrial enterprise are truly colossal, especially in America. The United Fruit Company of Boston, Massachusetts, has issued recently the fifteenth annual report of its medical department, and the general manager of the department, Dr. W. E. Deeks, states that about 5,000 copies of the report are distributed (largely by request) to individuals interested in tropical problems, to scientific institutions, and to libraries. The ramifications of the United Fruit Company are shown on a map at the beginning of the volume wherein are depicted the plantation districts in Central and South America, in Cuba and in Jamaica, together with the numerous routes of the company's steamships to the chief eastern ports of the United States and the routes taken by the Elder Fosse line to England and Rotterdam. In six tropical divisions and for two railroads the company maintains fully equipped hospitals. Nearly fifty medical officers are attached to these divisions and the services of fifteen consultants and others are retained in such a way that their names appear among the personnel of the medical department. From one seventy pages of statistics at the end of the report it appears that the medical department of the United Fruit Company undertakes responsibility for 223,000 people, that during 1926-29,000 were treated in hospital, 150,000 treatments were given in hospital dispensaries, and that 2,000 operations were performed with general anesthesia and 40,000 with local anesthetic. The bulk of the volume, however, is filled with original articles and reports by members of the medical personnel. Among these is one by Dr. Aldo Castellani, professor of tropical medicine at the Tulane University, New Orleans, on the classification of bacterial dysenteries and of dysentery bacilli. The articles are illustrated with pictures of diseased conditions of sundry parasite and with x-ray photographs, and at the beginning of the report photographs of the company's hospitals are reproduced. So varied are the duties for which the medical officers are called upon that the volume concludes with an article on general instructions for embalming. The report is a fascinating picture of the varied interest attaching to the medical side of a great commercial undertaking.

#### THE NSPCC

The annual report of the National Society for the Prevention of Cruelty to Children for 1926-27 is entitled *Progress*. The name is used not so much for the purpose of showing increase in such activities as prosecution but rather to indicate the measure of success attained in improving the status of children. Thus the number of children requiring help is falling, the gravity of offences against children is not increasing and the prosecutions show a marked decrease. The need for removal of children from their parents' care—on lack of care—is growing less and drink is no longer the principal cause of cruelty. On the other hand there has been development in the medical branch,

with its two ambulances in London for conveying children to hospitals, the number of patients seeking advice from the society is increasing and a special inspector looks after the interests of children on canal boats. The society hopes that in time Parliament will pass an Act excluding all children from the cinema. One direction in which the medical branch, under Dr. J. D. Saunders, is extending its activities is in persuading or helping parents to submit their children to operation or other treatment which has been advised by school medical officers or hospital surgeons. The inspectors frequently convey the child to and from the hospital in the society's ambulance. With the retirement from the directorate of Sir Robert Parr who succeeded the Rev. Benjamin Waugh in 1905 a second chapter in the history of the society may be said to have closed. The executive committee looks forward to increasing usefulness in the future.

#### THE LEPERS OF MAKOGAI

Dr. A. MONTAGUE, chief medical officer of Fiji, has sent us a small book on the above subject, written by Dr. F. Hall, who was medical superintendent of the leper hospital there from 1911 to 1920. Makogai and Makodraga are two islands lying some eighteen miles north east of Levuka, the old capital of Fiji. They used to be a coco-nut plantation, but when the Government of Fiji made the segregation of lepers compulsory, they were purchased and converted into a leper colony. Here are collected all the lepers of Fiji, a country scattered over an archipelago three hundred miles in extent. It promises to become the leper station of the Southern Pacific for New Zealand now sends its lepers there, as do Samoa, Niue Island, Tonga and the Cook Islands. The Gilbert and Ellice groups will probably do so in the near future. Makogai is two and a half miles long, it is a rocky cone rising nearly 800 feet above the sea, with four distinct and many smaller peaks running down to the sea in ridges. From the summit the spectator looks down on a series of sand bars fringed with palms, the sea of every shade of blue and green, marked with lines of white surf where the waves break on coral reefs and beyond, the deeper shade of the ocean studded with islands as far as the eye can reach. Near by is the rocky islet of Makodraga giving shelter and an excellent anchorage to the bay of Dehece where is the main leper hospital. Scattered over the island are the leper villages, five in number, each nationality having its own village with its native headman who is paid a small sum by the Government and is responsible for cleanliness and good order. Work is expected from and is beneficial to the lepers if they are capable of it and they are given the use of land and implements of cultivation, their surplus crops being purchased by the Government if they so desire. They have also their own store, run on a co-operative basis from which they can purchase almost everything they desire. They can, besides, earn money in connexion with the erection of new buildings and general public work at Dehece a bank has been established and is largely used for the deposit of saving. Sports and amusements are encouraged and there is abundant opportunity for fishing, beating model yacht racing, dancing, and so forth. Each denomination has its own church, well built and attractively furnished and a large building for a school has recently been completed. With regard to the prospects of cure, Dr. Hall states that if patients would only come early enough—at the first sign of an anaesthetic spot or macule or nodule—they could be cured. The hospital statistics are indeed very encouraging: of the 934 patients admitted since its opening in 1911, 444 have been discharged (100 on parole are cured, 19 unconditionally as cured, 325 repatriated), it is a very noteworthy fact that of the patients so discharged, only 6 have been readmitted owing

to renewed activity of the disease. The hospital consists of a number of detached buildings pleasantly situated in a palm grove, with a staff comprising a medical superintendent, a lay superintendent, twelve European sisters, a housekeeper, and a lunch driver. There is a well equipped laboratory, with every facility for bacteriological, microscopical, and photographic research. From Dr Hall's description and the photographs of the country which illustrate it, it is evident that they are in no way behind us in Fiji, and have some attractions of which we cannot boast.

#### THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH

As the Rockefeller Foundation has so many activities, it is useful for the sake of reference and information to have the recently issued account of the organization of the Rockefeller Institute for Medical Research,<sup>1</sup> founded in 1901, and its three departments—the general laboratories, the adjacent hospital, and that of animal pathology. The Department of the General Laboratories, of which, as well as of the Institute as a whole, Dr Simon Flexner is director, has five divisions: that of Pathology and Bacteriology, with a number of subdivisions conducted by workers with such well known names as Drs. Noguchi, Peyton Rous, Orlitzky, Silver, and Gates; the Division of Chemistry, under the guidance of Dr P. A. T. Levene; that of Experimental Surgery, under Dr Alexis Carrel; that of General Physiology, conducted by Dr W. J. V. Osterhout; and that of Biophysics, by Dr J. B. Murphy. The Rockefeller Hospital, which has been under the direction of Dr Rufus Cole since it was opened in 1910, investigates certain forms of disease, and the patients admitted are all suffering from the conditions under consideration at the time, the problems now being studied are acute respiratory disease, acute rheumatism, cardiac disease, nephritis and blood chemistry, respiration, and chicken-pox. The Department of Animal Pathology, opened in 1917 and presided over by Dr Theobald Smith, is on the shore of Carnegie Lake, opposite Princeton, New Jersey, and stands in a tract of 525 acres, the property of the Institute. All members of the scientific staff are paid, are required to be whole-time, to have preliminary training such as would be represented by an M.D. or a Ph.D. degree, and to possess a knowledge of research. The Institute does not confine its investigations to problems having an immediate application to human pathology, but considers that it can best serve medical science by devoting a great deal of attention to fundamental biological, physical, and chemical problems. Further, though the greater part of the research work is carried out in the laboratories of New York and Princeton, expeditions for the solution of problems such as that of yellow fever in South America, led by Dr. Noguchi, are undertaken from time to time.

#### CATS AND MICE, AND BEEF

One of the major problems of stock owners in this and other countries is the control of parasitic infections, and one of the most important groups of these diseases is that family which infests the lungs. In most cases the life-history is unknown, but a recent article in the *Journal of Helminthology*<sup>2</sup> on an analogous condition in domestic cats may assist in the solution of this problem. Cats in various parts of Britain suffer from a parasitic pneumonia caused by a minute species of roundworm. This worm lives in the parenchymatous tissue of the lungs, and there lays innumerable eggs, which hatch *in situ*. The larvae which emerge are swallowed, and pass to the exterior in the droppings, there they die, unless swallowed by mice which

feed on this material. Once swallowed, they migrate to the connective tissue and, encysting, wait until the mouse is eaten by the cat, when the cycle is completed. A somewhat similar state of affairs is found in the case of the common cat tapeworm, and laboratory workers throughout the world are familiar with the elongated cyst of that form in the mouse's liver. Biological control obviously depends on preventing the cat from eating mice—for once in a way rodents and hygieno conspire together to bell the cat. But if cats are not permitted to catch mice their chief function in life, at least in many humble homes, has disappeared. If they carry out their duties they suffer from a severe and often fatal pneumonia or from tapeworms. What, then, is to be done with our cats? Sir Arthur Keith's recent masterly survey, at the Leeds meeting of the British Association, of modern conceptions of evolution recalls Charles Darwin's story of cats and clover. It had been found that red clover will seed only when the plants are cross-fertilized by visits from bumblebees. (The clover crops in New Zealand were failures until bumblebees were introduced to fertilize them.) The nests of the bees, however, are raided by field voles, which greedily feed on the larvae they find there. Accordingly, the more field voles the fewer the bees, and consequently the poorer the next crop of red clover. But now villages cats kill (but do not eat) field voles, and so it follows that the greater the number of cats the fewer the voles, the more bumblebees, the better the clover crop, the richer the pasture, and the greater the production of beef. Our dinners, then, depend to some extent on the number of cats present. This might suggest an alternative occupation for an animal which obviously is suffering from two distinct industrial diseases, and perhaps in future its most important function in a man controlled world should not be to assist in the accumulation of wealth of Lord Mayors of London Town (that could be relegated in part to the more prosaic mousetrap), but in helping to maintain the traditional quality of the roast beef of England.

#### ROYAL SOCIETY OF MEDICINE SPECIAL DISCUSSIONS

At a conference of the presidents and presidents elect of the various sections of the Royal Society of Medicine, held three months ago under the chairmanship of the President, Sir James Berry, it was decided to continue the holding of special discussions during the forthcoming session. The following subjects were agreed upon, and are now announced in the calendar of the society for 1927-28, the dates will be settled later and notified on the day card. Two discussions will be held by the society as a whole—one on diet as a factor in the causation of disease, and the other on cleansing the colon. Twelve joint discussions will be held by the sections immediately concerned, their subjects are as follows: (1) chronic appendicitis in children, (2) treatment of pyuria in children, (3) the influence of naso-oral sepsis on the lungs and gastrointestinal tract, (4) nomoses in the tropics, (5) cutaneous mycoses in the tropics, (6) ocular complications of encephalitis lethargica, (7) surgery of the heart and pericardium, (8) new methods of treatment of pernicious anaemia, (9) treatment of varicose ulcers by intravenous injection, (10) effects of middle-ear disease on efficiency in civil and military life, (11) the pulpless tooth, (12) radiological pitfalls.

The fifth David Lloyd Roberts Lecture has been arranged by the Medical Society of London for Wednesday, November 16th, at 5 o'clock. It will be delivered by the Right Hon. Lord Hewart, Lord Chief Justice of England, who has chosen as his subject "Criminal law and insanity."

## Nova et Vetera.

### A SURGEON ENSLAVED

In the year 1689 John Taylor "at the sign of the ship in St Paul's Church-yard" offered for sale "A Relation of the great sufferings and strange adventures of Henry Pitman Chirurgion to the late Duke of Monmouth," etc (reprinted in Arber's *English Garner*, vol vii, 1883)

In this little book, of which there is a copy in the British Museum Pitman tells us that when on a visit to relations in Somerset he heard of Monmouth's landing and out of curiosity he and his brother and some friends rode to Taunton to see the Duke and his army, and found when they wished to return, that their road was blocked by the Government forces. Pitman accordingly yielded to the desires of his friends and acquaintances that he should attend to the sick and wounded in the rebel forces.

There does not appear any justification for his styling himself Chirurgion to the Duke nor does he tell us that he so much as had speech with him. He says that he was never in arms himself, but attended to the wounded and the sick at Sedgemoor on the fatal sixth of July, 1685, after which he fled homewards, but was taken prisoner and committed to Newgate, and afterwards, with his brother and many others was tried at Wells Assizes, when they were found guilty and sentenced to be hanged drawn, and quartered. This sentence was soon afterwards commuted to transportation to the Caribbee Islands.

Long before Botany Bay was discovered it was the evil custom of the English Government to sell its convicts into what was practically slavery in the plantations of the southern colonies of the North American continent and of the West Indies. The French also sent convicts and prostitutes to the Mississippi as early as the seventeenth century, as we may read in Prevost's *Manon Lescaut*. Not only were criminals so transported, but a large proportion of the Scottish prisoners taken at Dunbar were similarly treated and occasionally, at least persons whose presence in England was inconvenient were kidnapped and indentured as servants to the planters. Like all slaves, the hardness or comparative mildness or their lot depended largely upon the dispositions of their masters. Defoe probably had good grounds for his description slight as it is of the experiences of Moll Flanders in Virginia. He also had taken part in the rising under the Duke of Monmouth but, more fortunate than the subject of this article, escaped the tender mercies of Jeffries and of Kirke.

In those days it was not the practice of the Government to resume the care of the transported convicts either on the voyage or after arrival. The responsibility was transferred to purveyors of forced labour and to the planter in the colonies the Government being thus saved the trouble and the revenue possibly benefiting by the sums paid by the slave dealers—for so in fact they were—as purchase money. Pitman tells us that, in accordance with this practice,

my brother and I with nearly a hundred more were given to Jeremiah Neple and sold by him to George Penne a needy Papist that wanted money to pay for our transportation and therefore was very importunate with my relations to purchase mine and my brother's freedom.

It seems that Pitman's relations were people of substance for they paid Penne £60 on the condition that he should set the brothers free on their arrival in Barbados to which island they were travelling.

Penne was bound with his brothers in a bond to pay £120 if this and other conditions were not fulfilled. Unfortunately for the prisoners, the Governor and the Assembly of Barbados in an access of loyalty or pride pressed an act under which it became impossible for Penne to carry out his undertaking. By this savage law the period of service of all the Sedgemoor convicts was fixed at ten years without redemption. It was to be enforced under severe penalties. Attempts at escape were to be

punished by thirty-nine lashes on the bare back, the pillow, and branding on the forehead with FT—meaning "Fugitive Traitor."

The voyage from Weymouth to Barbados occupied five weeks. It was very sickly, and nine of the passengers died. On arrival in the colony the brothers were sold to one Robert Bishop. We are not told what kind of work they were put to, but Henry evidently practised his profession, although his master took all the fees. He would not, however, give them clothes, and their diet was "very mean"—5 lb of salt Irish beef, or salt fish a week for each man, and Indian or Guinea Corn ground on a stone and made into dumplings instead of bread. This diet which was not very suitable for the tropics, brought Pitman, so he says, "to a violent flux." His requests for an improvement and his protests against his treatment resulted in his being severely earned and put in the stocks in the full heat of the sun for twelve hours. It should be remembered that Barbados lies only about thirteen degrees north of the equator. Bishop got into money difficulties and could not complete payment for the slaves so that the brothers were returned into the merchant's hands as goods unsold. Soon after this, however, Henry's brother died and Henry determined to make an attempt to escape from the island.

It seems that he had a friend in Barbados to whom his relations in England sent money for his benefit and thus he was enabled to buy a boat and the necessary stores and to bribe assistants. The list of stores is interesting.

A hundredweight of bread a convenient quantity of cheese a cask of water some ten bottles of canary and Madeira wine and beer these being for the support of nature and then for use a compass quadrant chart half hour glass half minute glass log and line large tarpaulin, a hatchet hammer saw and nail some spare boards a lantern and candles.

Thus the party of eight, six of whom were Sedgemoor prisoners, which started in an open boat at midnight of May 9th 1687, was not badly provided. They were bound for the Dutch island of Curacao for they durst not land on an English possession for fear of recapture. The distance in a straight line is nearly seven hundred statute miles, making the voyage a daring adventure but there are many islands by the way at which the fugitives hoped to refill their water-cask and no doubt obtain food of some sort or another.

They stole out of the roadstead presumably Bridgetown, at night and despite a leaky vessel and bad weather and the impossibility of taking observations with the quadrant, going from island to island they reached the Isle of Saltatudos a week after leaving Barbados. Pitman nowhere tells us how or where he acquired any knowledge of practical navigation. He attributes his failure to get observations of the sun to the movement of the boat and the nearness of the sun to the zenith. It was then May, and the latitude of Saltatudos is given by him as 11° 11' N. Here they found a party of twenty six privateers who had somehow been left behind by their shipmate. These men tried to persuade Pitman and his companions to leave the island with them in canoes or piraguas as they were called locally, and on their refusing the privateers burnt the boat, used the nails thus obtained to fasten top-sides or weather-beards on their canoes and all but four sailed away leaving the others marooned.

The island of Saltatudos by which name it was known to the English, was so called on account of its natural salt-pans which were visited by the Spaniards and others at intervals of many months in order to obtain salt. By the Spaniards it was known as Tortuga from the number of turtles that were found on its shores and this name it still keeps. It is some twelve miles long by three broad and is situated about fifty miles from that part of the Spanish Main which is now known as Venezuela and about four hundred miles from Barbados. There are a number of places of the same name in the West Indies and Central America the best known being another island lying to the north of Haiti. Pitman called his island uninhabitable, but though it was then and still appears to be uninhabited, it proved to be quite habitable for the turtles and numerous bird and fish provided abundant food and there was a good supply of fresh water. The lack of farinaceous food

was felt, however, and the diet of turtles and their eggs brought on diarrhoea, which Pitman cured with

"an opiate tincture which I had provided on another occasion. For before we came from Barbadoes, I thought of a way to deliver ourselves out of our enemies' hands, in case we should be taken, without shedding of blood. And it was this. I dissolved a sufficient quantity of opium in a bottle of rich cordial water, which we carried with us in the boat intending to give it to those persons that should take us, which I supposed they would readily drink, and by that means would be overtaken with so profound a sleep that we should have opportunity sufficient to make our escape from them."

It was as well that this tincture was put to a less dangerous use. There were no trees on the island, but plenty of bushes, which provided fuel and some edible fruits. One plant, which he calls a "cucurbit," provided a juice which scoured their clothes in place of soap, moreover, its leaves when fermented furnished a sweet juice "like the syrup of baked pears," from which they prepared "a most pleasant and spirituous liquor to drink. The innermost part of the body or stump we cut into slices, and ate it like bread." This admirable plant, which Auber suggests might have been an agave, reminds us of the natural products which the Swiss Family Robinson found ready to supply every want. A substitute for tobacco was found in a certain herb which he called wild sage, and crab's claws served for tobacco pipes. He does not complain of the heat, although the months of May, June, July, and August, during which he remained on the island, must have been hot enough in the absence of any effective shade. At the end of this time a privateer ship appeared and took on board the four men the canoe party had left behind and then inquired "Which was the Doctor?" When Pitman was pointed out they invited him to sail with them but refused to take his fellow-refugees from Barbados.

"When we came to the man of war, I was very honourably landed up the side, the trumpets in the meantime sounding, and very kindly received and welcomed aboard by the Captain and Doctor, who invited me aft into the Great Cabin where I was not only feasted with wine and choice provisions but had given me by the Doctor a pair of silk stockings, a pair of shoes and a great deal of linen cloth to make me shirts, etc."

If the buccaneers were so villainous as some have thought, their name is nevertheless, like that of Byron's Corsair, "linked with one virtue"—a due appreciation of the medical profession, as was noticed in an article on "Buccaneer Surgeons" in the *JOURNAL* of August 26th, 1922 (p. 397). The privateers took him to Providence in the Bahamas where they burnt their ship and shired their boats, and after some stay Pitman sailed to New York, and thence, in a vessel bound for Amsterdam, he reached the Isle of Wight, and so returned home to find that his friends had procured his pardon. He seems to have set up as a vendor of nostrums, for at the end of the original work there is a page of advertisement of the "Quintessence or Powers of Scurvy grass, both plain and purging," price one shilling a bottle, of "Magisterium Anodinum" to cure pain, price one shilling a box, of "Spiritus Catholicus," a kind of purgative, and Pillule Cathartice. "These medicines are all prepared and sold by Henry Pitman at the sign of the ship in St. Paul's Church Yard."

There we leave him. His name does not appear in the books of the Barber or of the Apothecaries Company, and it seems probable that he was unqualified, for he nowhere claims to be a physician. He seems to have been a real person, for in the *Calendar of Treasury Books*, vol. viii, pt. I, we find, under date 1685, the following entry: "Co. Somerset Wells. Prisoners delivered for transportation to Jerom Nipho. Hen Pitman," and among a number of other names we find that of William Putman, which might well be a misspelling of his brother's name. The following entry in the *Calendar of State Papers, Domestic*, William and Mary 2, 1690-91, p. 410, suggests that Henry Pitman did not make a fortune out of his quack medicines, supposing it to refer to him: "1691. June 12, Whitehall. Passes for Thomas Wilson, James Dickenson, Henry Pitman and William Muckloe to go Gravesend for Barbadoes."

His former companions after many adventures, including

captivity and all treatment by the Spaniards, returned home at last, as related in an appendix to Pitman's book.

It has been suggested that Defoe had read Pitman's "Relation," and that when he wrote *Robinson Crusoe*, thirty years after this book was published, he had in view Tortuga and not Juan Fernandez. It is true that the situation of Tortuga in the Caribbean sea and near the mouth of the Orinoco corresponds well with Defoe's description of Crusoe's island, whereas Juan Fernandez lies far away in the Pacific.

But such attempts at identification are futile. Pitman was by no means the first to be marooned on an uninhabited island, and neither from Pitman nor from Sellink is Defoe likely to have got the wealth of convincing detail which he gives us with such wonderful verisimilitude. Probably he could get more out of an hour or two's conversation with a returned mariner, and remember the details more accurately than an ordinary person could after a year's companionship.

## WELFARE OF THE BLIND

### AN OFFICIAL HANDBOOK

THE ADVISORY Committee on the Welfare of the Blind, of the Ministry of Health, has just issued a *Handbook on the Welfare of the Blind in England and Wales*.<sup>1</sup> In his preface the Minister, Mr. Neville Chamberlain, writes

"The handbook gives an attractive and sympathetic account of the principles which have been found most effective in helping the blind, and of the way in which they have been carried out in practice. I believe it will not only prove valuable to those who are already engaged in the work, but that it will make a wide appeal to the public, who have always demonstrated their sympathy with those deprived of sight, and some of whom may perhaps be induced after perusing this book, to offer their services in one of the many ways in which they will be welcome."

After reading this handbook we, too, are convinced that the committee has done a most excellent piece of work. In the space of thirty-four well printed pages there is a wealth of information set out in a most attractive style. Here is everything that the sympathetic person, the social worker, the educationist, and the economist can desire to know about the blind—how best these may be helped, and how they are being helped.

### Definitions and Returns

First there is a statement of the definitions of blindness, as they affect school children and adults, and a note of some of the difficulties that attend this determination. The definition for school children "too blind to be able to read the ordinary school books used by children" has some measure of prevention attached to it, so this definition is wider than that for adults, "so blind as to be unable to perform any work for which eyesight is essential," which has a purely economic bearing. The two definitions do not coincide, and cannot, for their objects are not the same. Care is therefore needed in the choice of training of elder blind children who, though scholastically blind, may not be economically blind.

The latest return of the blind shows that there are 46,822 in England and Wales, an increase of over four thousand since the last year. The increase is due to better registration. In the past few years one of the most frequent causes of blindness was ophthalmia neonatorum, the success of preventive measures has greatly reduced its incidence, so that there will be an increase in the proportion of blindness at later ages.

### Growth of Service for the Blind

An interesting account is made of the growth of services for the blind. France has the honour of providing the first public institution in the Hospice des Quinze-Vingts in Paris, founded by St. Louis in 1260, principally for blinded soldiers. Our first institution of the sort was founded by Edward Rushton in Liverpool in 1790, he became blind on a slave ship while tending negroes with trachoma. France produced Braille and his embossed writing, England Dr. Moon and his type, which is the easier for adults to learn. England produced Mr. H. M.

<sup>1</sup> *Handbook on the Welfare of the Blind in England and Wales*. Ministry of Health, London, H.M. Stationery Office, 1927. 6d net.

Taylor, the inventor of mathematical and chemical formulae which make it possible to produce scientific tools for the blind, and another Taylor whose slate for teaching mathematics is used in all schools. The first legislation for the blind was in Queen Elizabeth's time, it enjoined care by relatives or by the overseers. In recent years there has been improved legislation, the codification of the Education Acts, and the Blind Persons Act. The effects of the measures are stated in the handbook.

The duties of the local statutory authorities, education and county are now clearly defined. All the 146 councils of counties and county boroughs in England and Wales (except one just constituted) have made schemes under the Act. A comprehensive scheme includes provision for children under school age, education and training of children and of young persons and adults, employment in workshops, as home workers, hostels for the blind, homes, attention to the unemployable blind, home teaching, and registration. The work cannot be done wholesale, it demands individual attention, for the blind vary as much as normal persons, and even more.

Commenting on these provisions the remark is made, "It is obvious in the interest of the child that it should remain at home unless the home conditions are so bad as to necessitate its removal." When the child is at home and under school age much may be done to guide parents or a blind child. Schools for the blind are now pretty complete. Training is twofold—for the children leaving school, and for those blinded in later years. Both have their own special problems. As a prerequisite it is necessary to make sure that the person is likely as a result of training to become reasonably efficient, and that there are openings for remunerative employment for him at the end of the training. Much avoidable suffering may be caused to the blind by neglect of these considerations.

Work may be done in workshops where these are near to the blind person's home or else it must be done at home. The handicap of blindness prevents most persons from earning a livelihood if they are paid only what they earn. There must be augmentation of these earnings. How best to arrange for this and preserve the highest inducement to earn has been a problem that has needed much thought. There are given in an appendix the findings and recommendations. The home worker has special needs, he has to be helped to find his market, and there are here valuable opportunities for good Samaritans in helping him by sales of work garden parties, and the like. Some agencies have promoted motor shops for the sale of these goods. In any case his work must be real work and no pastime. Some blind men have worked their way, by reason of their exceptional gifts in church, law, politics, and elsewhere. The name of Milton need scarcely be cited to show how one overcame his affliction, and lived so "that I may see and tell things invisible to mortal sight." Few works of greater promise for the blind can be undertaken than constant experiment with a view to finding new occupations for them and scientific study of the work for which they are specially fitted.

#### *The Unemployable Blind*

The tale of the unemployable blind is a heavy one. 67.6 per cent. are so classed in the latest return. Some 10 per cent. of the whole suffer other physical or mental defects. A few of these blind persons have means of their own, some have husbands who support them, others have old age pensions (for which they are eligible at 50) or pensions from one of the societies. Some receive disablement benefit, or workmen's compensation. Some are children in good homes, or parents in children's homes. Others are lonely, helpless, and destitute. The measures for the relief of these persons are considered. In the last resource "it will rest upon the local authorities under the Act as an essential part of their duty to secure that reasonable provision is made for these persons."

#### *Home Teachers*

The pivot of the social work for the blind is the home teacher. There are 360 of them. Their work is to secure that all the blind who need visiting should receive visits

systematically. They teach blind writing and reading, pastime occupations, hygiene, engage in welfare work, and introduce solitary blind to social centres. "There is no more promising outlet for the efforts of volunteers interested in the welfare of the blind than to assist in this sphere of work." But the efforts must not be haphazard, so volunteers should get their work co-ordinated by one of the local voluntary agencies, of which a list is given.

The concluding chapters deal with the organization of administration, with the place of voluntary organizations, and with the prevention of blindness. Here will be found a recommendation to read the report of the committee on "The causes and prevention of blindness" issued in 1922, which we can heartily endorse.

## India.

### TUBERCULOSIS IN INDIA

THE increase of tuberculosis in India during the last fifty years was the subject of a paper read by Dr. C. Frimodt-Møller at the Fourteenth Indian Science Congress at Lahore last February, and since published in the *Indian Medical Gazette*. Dr. Frimodt-Møller attributed it primarily to the climatic conditions and especially to the prevalence in certain areas of heavy rainfall and monsoon storms. That this is not the only cause is indicated by the severity of the disease in certain cities, such as Hyderabad (Deccan), which is favoured by a good climate, and seems to have been comparatively free from tuberculosis forty years ago. The educated classes and the more prosperous communities are believed to be becoming increasingly infected in spite of their higher level of hygiene for this their greater exposure to infection in educational institutions is blamed. Moreover, the larger industrial centres intensify dissemination by drawing to the cities considerable numbers of the inhabitants of villages who, having contracted the disease, return home and become dangerous sources of infection for the non-immune rural populations. Improved travelling facilities are also incriminated in this respect, and in India, as elsewhere in the tropics, it is demonstrable that tuberculosis travels along the chief lines of communication. Dr. Frimodt-Møller advocates therefore, the establishment of at least one large sanatorium in each province where the climatic conditions are suitable. These institutions, he adds, might well become centres of scientific research, with a view to determining the best ways of applying the various forms of treatment to the special requirements of Indian patients; they would also function as educational centres for medical graduates and students. Special tuberculosis hospitals of cheap and light construction should, he thinks, be erected outside the chief towns, and larger hospitals with research facilities should be constructed in the provincial capitals. He advises postponing the establishment of dispensaries until more adequate residential accommodation is available and suggests that the dispensaries already in existence should function mainly as clearing stations for diagnosis, with special duties in regard to the detection of the sources of infection and the devising of co-ordinated preventive measures. He recommends further that a tuberculosis bureau should be organized with a view to teaching the public the dangers of infection and the use of prophylactic procedures.

### TREATMENT OF LEPROSY

Dr. Milton C. Lang, medical superintendent of the Chundkuri Asylum, Central Provinces, India, in his annual report for 1926 summarizes the results of the quarterly examinations of the inpatients at this asylum, and states that there was an average of 183 patients under treatment for a whole year, receiving two injections weekly of either pure hydriocarpus oil with creosote and olive oil, or the diluted esters of hydriocarpus oil. Of these patients an average of 85 showed improvement, 69 remained stationary, and 29 became worse. Dr. Lang considers, therefore, that treatment is very much worth while, even in the present circumstances. In the large majority of the so-called stationary cases the disease has almost

run its course, but, by treatment, the patients can be made bacteriologically negative. During the last year about one hundred patients have been removed from the treatment list, as they have passed into the class of "burnt out" cases, they have the scars of leprosy such as the loss of fingers and toes, but they are no longer infectious, and resemble the man who shows the pox marks of small-pox but who no longer has the disease. During the current year much better results are expected. The luteal lepers will first be treated for syphilis and their progress checked by means of the Kahn test. Dr Lang remarks that Muir and others have shown repeatedly the absolute necessity of removing predisposing causes, such as hookworm, malaria, syphilis, and other debilitating diseases, and reports an illustrative case. A woman who was progressing particularly well received three weeks' leave of absence. When she left the institution she would hardly have been recognized as a leper. While away she had a severe attack of malaria, which was untreated, and subsequently thickening on her liver developed, with new nodule formation. Had the malaria been radically treated at once this would not have occurred. Dr Lang states that each year all patients receive the carbon tetrachloride mass treatment for hookworm. Extensive stool examinations during the past year showed the incidence of this infection to be practically nil. He adds that hookworm is not very common in the district, but the mass treatment helps to remove any that exists. The eradication of malaria and its sequelae is more difficult, but by persistent efforts considerable improvement is expected. It is now realized that not only must the leprosy be treated, but predisposing causes and debilitating diseases must be removed, when the leprosy will progress more rapidly toward arrest, if these diseases are not dealt with extensive and long-continued treatment is valueless and tends to discredit a method which has been proved successful. During the last quarter ten patients were classified as cured of the disease—that is, so far as the physical and bacteriological examinations were concerned, they were free of leprosy. These are not called cured, but arrested cases, though there is good reason to believe that if their living conditions are suitable and they take proper care of themselves they will remain free of the disease for the rest of their lives.

#### MEDICAL PROGRESS IN BIHAR AND ORISSA

There has been a steady increase in the number of hospitals and dispensaries in Bihar and Orissa during the three years 1923, 1924, and 1925. At the beginning of this period 485 institutions were at work, and during the triennium 165 new ones were opened and 52 were closed. Most of these new buildings were dispensaries in rural areas established by local authorities. An attempt is being made to provide one dispensary for each police station. In his report for the three years Colonel H. Ainsworth, I.M.S., Inspector-General of Civil Hospitals in Bihar and Orissa, states that travelling dispensaries have not been successful in this province and their number in the period under review was reduced from sixteen to three, two of which were at work in the Angul district and one in Saran. The number of patients treated annually in these dispensaries fell from over 50,000 in 1923 to 7,000 in 1925. Colonel Ainsworth suggests that in place of these dispensaries, which are very difficult to staff, greater inducements should be offered to medical practitioners to settle in the larger towns and villages where dispensaries do not exist. In some places the local authorities subsidize doctors for a term of years until they are able to establish themselves in practice. During the period under review over 10,000 patients were treated at the Patna General Hospital, over 7,000 at the Pilgrim Hospital, Gaya, and nearly 6,000 at the Cuttack General Hospital. The work in the outdoor departments of the hospitals and dispensaries increased steadily, an average of nearly 4,000,000 patients being dealt with as compared with rather less than 3,000,000 in the preceding triennium. This satisfactory development is largely due to the provision of more dispensaries in rural areas. Cholera hospitals were established at Puri and Gaya, and in the case of a severe epidemic both can be rapidly extended. A leprosy committee has come into being to supervise the

work in connexion with this disease. It has been decided to appoint a medical officer as an expert on leprosy in the provinces, and to establish special clinics wherever required to carry on propaganda, with a view to the discovery of early cases. The Radium Institute at Ranchi has increased considerably in popularity and new buildings have been erected to accommodate Indian families, Europeans, and poor patients of all classes. The quantity of radium at the Institute is 547 milligrams of the bromide and 606 of the element, this considerably exceeds the amount available elsewhere in India. A scheme to facilitate radium treatment by medical practitioners in India has been drawn up, but requires considerable financial support before it can be launched. During the triennium under review an attempt has been made to render the provinces self-supporting as regards the supply of medical officers. A medical school has been erected in Darrbhanga and the local hospital has been enlarged to provide the necessary facilities. A college was also erected at Patna to deal with the first-year medical students, these were to be transferred last year to Darrbhanga, permitting the Patna institution, which is affiliated to the University, to accommodate more advanced medical students. In the present absence of facilities at Patna for teaching in midwifery and mental diseases, arrangements have been made for students to receive clinical instruction in midwifery at Bangalore, and in mental diseases at the Indian Medical Hospital at Kanke.

#### PASTEUR INSTITUTE, SHILLONG

The tenth annual report of the King Edward VII Memorial Pasteur Institute and Medical Research Institute at Shillong, in Assam, shows that 1,417 persons completed treatment for rabies during 1926 as compared with 1,176 in 1925, of this total 72 were Europeans. In 12.3 per cent of the cases the bites were caused by jackals, the hydrophobia rate for which was calculated to be 52 per cent, as compared with 0.41 per cent in those bitten by dogs. Of fourteen patients who died from hydrophobia, seven were bitten in the face. During the year antirabic vaccine was issued to medical and veterinary officers for the prophylactic treatment of bitten animals. Research work in kala-azar was continued, and the effects of two new preparations—aminostiburea and novostiburea—were tested. Very good results have followed the intensive campaign during the last year or two against kala-azar based on experimental work in the Institute; the number of patients suffering from this disease having diminished. Early in 1927 a preliminary note on a quick and simple test for distinguishing malaria from kala-azar and other fevers was published by Lieut.-Colonel L. C. Hodgson, I.M.S., director of the Institute and two of his colleagues.

## England and Wales.

#### VITAL STATISTICS FOR 1926

THE Registrar-General's *Statistical Review of England and Wales for 1926*, Tables, Part II, can now be obtained from H.M. Stationery Office price 5s. It contains statistics of the population, marriages, births, passenger movement, parliamentary and local government elections, and vital statistics of the British dominions. The total population in thousands of Great Britain and Ireland was

	1926	1925	Increase + or Decrease - per cent
England and Wales	39,057	38,893	+ 0.46
Scotland	4,897	4,893	+ 0.08
Northern Ireland	1,255	1,257	- 0.02
Irish Free State	2,970	2,935	+ 0.59
Total	48,180	48,025	+ 0.34

In England and Wales the male population increased by 0.52 per cent and the female population by 0.40 per cent. The number of marriages solemnized in England and Wales during the year was 279,860, equal to a rate of 14.3 persons

married per 1,000 persons living. This rate is 0.9 per 1,000 below that in the previous year end, with the exception of the war year 1917, is the lowest rate recorded since 1886. The births registered during the year numbered 694,563 and were equal to a rate of 17.8 per 1,000 population. This rate was 0.5 per 1,000 below that recorded in the previous year end, with the exception of the war year 1918, is the lowest rate recorded since the establishment of civil registration. Not only has the birth rate declined but the actual number of births is the lowest recorded since 1860 when the population of England and Wales was only 19,922,000, or about one-half of the estimate for 1926. The proportion of male to 1,000 female births was 1,041. This proportion showed a great increase during the war years and reached a maximum of 1,060 in 1919, since then the decline has been almost continuous and the rate is now approximating to that which prevailed in the period immediately prior to the war.

#### TOWN DWELLERS' RESISTANCE TO TUBERCULOSIS

The relatively high resistance of town dwellers to infection by the tubercle bacillus forms an interesting subject for investigation. Dr R. M. F. Picken, medical officer of health for Cardiff—the city chosen for next year's Annual Meeting of the British Medical Association—has begun, in his report for 1926, to collect data for elucidating the problem, and he hopes to carry out investigations with Professor Lyle Cummins and Dr Gidechrist, into the effect of active immunization on infants specially exposed to infection. Dr Picken points out that, according to one theory, those who have been repeatedly exposed by town life to small doses of infection in childhood acquire a certain degree of immunity. On the other hand it has been supposed that town dwellers inherit their resistance from an immune ancestry who have been able to survive to reproductive ages in unfavourable conditions only because they possessed this power. It is hoped that by recording the birthplace and parentage of persons suffering from tuberculosis over a series of years, and by obtaining information of the fate of infants born into tuberculous households it may be possible to arrive at definite conclusions on the question of urban or rural nurture in relation to heredity and exposure to infection. Such conclusions would have an important bearing on the need for special anti-tuberculous measures. The statistics in Dr Picken's report do not take one very far, but this is only to be expected with a chronic disease such as tuberculosis, in which obervations over a series of years are alone of value. Moreover the exceedingly rapid growth of Cardiff until comparatively recent years makes it improbable that many of the present adult generation had parents who were both born in the city. With regard, however, to infants born in 1926 in tuberculous homes, though the numbers are comparatively small, it appears that the mortality among them was approximately double the infant mortality of the city.

#### LONDON COURSES IN NEUROLOGY AND PSYCHIATRY

A post-graduate course on diseases of the nervous system will be held at the National Hospital, Queen Square, London, from October 3rd to November 25th. The general course will consist of clinical lectures and demonstrations, teaching in the out-patient department and pathological lectures and demonstrations. The fee for this course will be £5 5s. A course of lectures on the anatomy and physiology of the nervous system will be arranged if there are sufficient applicants, fee, £2 2s. A course of clinical demonstrations, chiefly on methods of examination of the nervous system, will also be given, fee £2 2s. Tickets entitling to attend the Out-patients' Clinic only (£2 2s for three months) may be obtained from the secretary of the Medical School, National Hospital, Queen Square, W.C.1.

A course in advanced psychiatry will be held at the Maudsley Hospital during the same period. Times of lectures and demonstrations will be so arranged that it will be possible for medical practitioners to attend both courses. The course in psychiatry consists of three parts: clinical lectures illustrated by cases, demonstrations upon the investigation of recently admitted cases and discussion of fully investigated cases. The fee for the whole course

is £5 5s. Those wishing to take any part separately should communicate with the Director of the Medical School, Maudsley Hospital, Denmark Hill, S.E.5.

#### EXETER MEMORIAL TO MR E. J. DOMVILLE

At St David's Church, Exeter, on September 4th, the vicar dedicated three carved oak seats and a bench as a memorial to the late Mr Edward James Domville, O.B.E., M.R.C.S., who was long closely associated with that church and was mayor of the city in 1893. Mr Domville was consulting surgeon to the Royal Devon and Exeter Hospital, and for many years took an active part in the work of the British Medical Association, both locally and in central committees and the Council. He died in November, 1925, and the funeral service was held at St David's Church. The memorial seats, bearing an inscription are in the north transept below a stained glass window commemorating his only son, David who died several years ago. They have been designed by Mr W. D. Caroe, who was architect of the church.

## Scotland.

#### THIRTY YEARS' PROGRESS IN PUBLIC HEALTH WORK

SIR LESLIE MACKENZIE, at the opening of the new pavilion of the M. Kelvie Hospital, Oban, delivered an address on the public health movement in Scotland since 1899. He said that the public health movement in Scotland really began about that year. The many problems covered by the official names "maternity service" and "child welfare" were increasingly realized by the public imagination. With the new extension of the hospital which had just been opened the corporation of Oban would possess an effective modern hospital of 42 beds. The new extension would permit the local authorities to deal with cases of infectious diseases such as measles, ophthalmia neonatorum, and whooping-cough occurring in children. Thirty years ago compulsory notification was made universal in Scotland, and the list of notifiable diseases now approached thirty. In these thirty years medical men had notified 1,450,818 cases, and of these 770,000 had been removed to hospitals under the management of the local authorities for public health. These great numbers gave an idea of the problem that constantly faced public health authorities in Scotland. Notification of pulmonary tuberculosis had been carried out since 1906, and 137,705 cases had been notified in that period. The annual figures had been as high as 9,000, though recently there had been a falling off till, in 1926, the number notified was only 6,669. The total notifications for all cases of tuberculosis had been 189,159, of which 63,354 had been removed from their homes for treatment. In the early years of notification the annual figures for typhoid fever had been as high as 5,600, but in recent years they had never exceeded 800 and in some years the cases of this disease had fallen below 400. It appeared, therefore, that typhoid fever was now under effective control. As to typhus fever this disease had fallen off so much that occasionally a year passed without a single case. In 1926 only one case of small pox had been notified in Scotland, and small pox also was therefore under effective control. Finally new methods of dealing with enteric fever and diphtheria had been introduced and were already beginning to have effect in diminishing these diseases.

#### CENTRAL MIDWIVES BOARD EXAMINATIONS

At the examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, which concluded out of 91 candidates who appeared for examination 63 passed. Of the successful candidates 15 were trained at the Royal Maternity Hospital, Edinburgh; 27 at the Royal Maternity Hospital, Glasgow; 5 at the Royal Maternity Hospital, Dundee; 4 at the Royal Maternity Hospital, Aberdeen; 13 at the Queen Victoria Jubilee Institute, Edinburgh; 2 at the Elsie Inglis Hospital, Abberhill; 5 at Stobhill Hospital; 3 at the County Maternity Hospital, Bellshill, and the remainder at various recognized institutions.

## Correspondence.

### EPIDEMIOLOGY OF POLIOMYELITIS

SIR,—I note with regret the terms in which Dr James Collier (September 10th, p 468) has felt compelled to challenge the accuracy of a summary of his views on the epidemiology of poliomyelitis contained in a paper of mine on that subject in the JOURNAL of August 27th last (p 347).

The summary in question and the deductions drawn therefrom were formulated after a most careful study of Dr Collier's opinions, as expressed in the JOURNAL on April 23rd (p 751), and were certainly not intended to impute any wilful inaccuracy of statement to him, nor indeed do I think that the careful reader will find anything of the kind in them.

Although our respective views on these disputed points are on record in the pages of this journal for all who may be interested to assess their relative value and accuracy, yet since the subject is of more than purely academic interest and importance it is as well that the issues should be made as clear as possible, and that any confusion arising from merely verbal obscurity should be dissipated. Therefore, although there is nothing in my paper which I wish to modify, the challenge to its fairness and accuracy is so emphatic that I may be allowed to give the authority upon which the disputed passages are based.

In the first place it appears from his letter that Dr Collier and myself are no longer at one in our use of the term "carrier." I take this to refer to an individual who, while he harbours a given pathogenic organism, is himself free from the disease to which this organism gives rise. By a "carrier epidemic" I understand the prevalence at a given time and place of numbers of such individuals harbouring some particular pathogenic organism, the associated disease being itself not present.

Throughout his paper Dr Collier gives indications that hitherto he also has understood these terms in the above sense, yet in his letter he appears to use them in another and a less precise sense, and one involving a material change in his views on the question of case-to-case infection. Thus, in his paper he says "though the virus can be obtained from the mucous membrane of cases for some days after the disease has appeared, and monkeys can be inoculated with the disease from this virus, that does not mean for one moment that a patient even in the early days of his illness can deliver an infective dose of the virus to another person. There is strong evidence that a case of poliomyelitis is not infectious, and that a carrier, especially a recent carrier, may be very infectious." Further, "the disease is never transmitted by the one who is suffering from it, but only by the carriers." And finally, "When an epidemic of poliomyelitis occurs in a community it is preceded by a carrier epidemic in which for a time no cases occur but many carriers are made, and with the increasing advent of carrier infection to susceptibles the virulence of the infection is raised and at last definite cases occur. Such a preceding carrier epidemic best explains the curve of incidence in an epidemic, with its rapid blaze, high peak, and rapid fall, all the cases occurring within a few days and then no more cases." It follows that when a case of poliomyelitis occurs in a semi-isolated community such as a school which has been assembled, say, for several weeks, there has already been a carrier outbreak going on for some time, and all the boys are already infected as cases or carriers or they are immune. The actual cases are not infectious, and all the damage that can be done has been done so far as the boys are concerned.

These statements, which might be added to considerably, not only afford ample confirmation of the accuracy of my summary but indicate that the writer uses the term "carrier" in the accepted sense, regards the carrier as the sole vehicle of infection, and places sufferers from poliomyelitis in a separate category. In his letter, however, Dr Collier now says that by carriers he also means sufferers from poliomyelitis in the incubation period. "Is not every case of poliomyelitis of necessity a carrier during the incubation period," he asks, "since this is a nasopharyngeal infection and readily communicable by droplet infection?"

In short, it is by virtually abolishing the distinction between carrier and sufferer—between carrier epidemic and disease epidemic—that Dr Collier impugns the accuracy of my summary of his views. What are we to understand by a carrier epidemic on this new definition? May it be nothing more after all than an outbreak of definite cases of poliomyelitis during their few days of incubation? If this be so, nothing is left of the theory of the carrier epidemic and of the non-infectivity of cases of poliomyelitis.

The other objections to my paper appear to be based upon similar qualifications of previously expressed views, and they are, in my opinion, fully met by the quotations given above. It remains only to refer to the question of the figures in the Stokes Rivers epidemic.

I cited that outbreak as evidence that in the matter of day-to-day case incidence, multiple cases in households, and the non-immunity of persons not infected at the outset, epidemics of poliomyelitis do not present the features ascribed to them by Dr Collier and do not allow of the interpretation he has put forward. The total case incidence is a matter of no importance in this connexion and the difference in our respective figures is due to the fact that Dr Collier has included nine cases described in the original report as doubtful, thus bringing his total to 45, while I have confined myself to the 36 cases in which the medical officer of health was satisfied as to the diagnosis.

It is surely clear enough that my criticism of Dr Collier's reference to the outbreak lies in his description of it as "a swift scourge which could lay low in a few days" whereas actually the total of 36 (or 45) cases occurred over a period of forty days, not more than two fresh cases developing on any one day. I still believe that this criticism is valid and material to the question at issue between us—I am, etc.,

London W 1 Sept 11th

F M R WALSHE

### TONSILLECTOMY AND CONSERVATIVE TREATMENT

SIR,—Dr Walker in his letter on tonsils and rheumatism (September 10th, p 470) is most happy in his description of the practice he adopts in the nose and throat department of the Aberdeen Dispensary—namely, that "of attempting conservative treatment whenever there seems to be some prospect of success," though in the majority of these cases he is "forced eventually to resort to tonsillectomy." This attitude and this experience are in accord with my own and those of most moderate-minded practitioners.

In the attempt to succeed with conservative treatment I have found that a penetrating local application of iodine has been very efficacious, even to the extent of "doing me out of" an expected tonsillectomy. The application consists of iodine 5 grains, rectic ether (acid-free) 2 fluid drachms, and glycerin up to 1 ounce. This has to be well shaken and brushed into the tonsils. The rectic ether adds to the pleasantness of the taste and appears to carry the iodine into the depths of the tonsillar crypts. I have verified this by painting tonsils with this solution and causing the patient to swallow several times previous to their removal. After the removal I divided them at right angles to the surface and dropped on the cut part a solution of starch. A reddish-purple tint was then, and only then, produced, extending very deeply into the crypts. The experiment was controlled by the application of starch to sections of tonsils not painted with iodine, when no such coloration was visible.

As a prophylactic gargle for the tonsils *thymol water* has a great reputation, which I think is quite justified. A culture taken by Dr Carnegie-Dickson from the tonsils after a gargle of plain warm water was found to afford a copious crop of colonies of the usual microbial inhabitants of the mouth. After a gargle with thymol water and again with simple warm water such colonies were extremely few. A condition of such effects is that the thymol water should not merely be slopped about the root of the tongue, but should be allowed to pass into the back of the throat while the head is thrown well back and the movement of swallowing performed without, if possible, allowing the fluid to slip down the gullet.

Caseous masses filling the crypts may be cleared away by means of a fine dental syringe with the point bent at a right angle (charged with hydrogen peroxide (equal parts of the ten volume solution and warm water). Such accumulations are often concealed behind the plica triangularis. The relief afforded by such syringing is often very considerable and prolonged. In the case of a gentleman who had come over from Australia with such pain and discomfort that nothing would convince him that he was not suffering from cancer, the relief following the washing out of a mass of the size of a pea was so extraordinary that he jumped up and exclaimed that his trouble had completely gone.

In giving the conservative treatment a fair chance these simple suggestions will be found useful while still leaving a sufficient number of tonsillectomies for those who wisely perform the complete enucleation in appropriate cases, seeing the gratifying results as regards local comfort and general health—I am, etc.,

London W1 Sep<sup>r</sup> 14th.

JAMES DENNIS GRANT

#### A TREATMENT FOR ASTHMA

Sir—I regret very much that your powerful JOURNAL should, in its leading article of August 27th (p. 355) have dammed with such "faint praise" the valuable results of Professor Storm van Leeuwen's investigations with regard to the causes and treatment of asthma and the other allergic diseases.

Your criticism on Storm van Leeuwen's alleged views as to kapok pillows is in reality a strong vindication of his theory of the importance of moulds in asthma. He has never said that *penicillium* is an exciting cause of asthma. He simply regards kapok as a good culture medium for the *Aspergillus fumigatus*. In the Swiss mountains, his and similar moulds are not found; consequently it is a matter of indifference whether the pillow used is kapok or feathers, provided it has not been infected before being brought to the mountain heights. The freedom of asthmatics from symptoms at the *haute altitude* is no doubt due to the absence of these moulds and other allergens.

I have had personal experience of Professor Storm van Leeuwen's treatment in an allergen-free chamber as I slept in one for over four weeks in his clinic at Leiden. I was not a pure climatic case, and did not gain entire freedom from asthmatic attacks while sleeping in it. I did the great majority of the other patients who were in the clinic at the same time as myself, but the number and severity of my attacks decreased and my general health improved markedly.

The mere fact that it is alleged that cacti alone can be grown in allergen-free chambers is no proof at all that the chambers are unhealthy for man. Who tried to grow the plants? A good doctor is not necessarily a good gardener. Owing to the rapid change of air in the chamber excessive evaporation goes on. Was this allowed for? Allergen-free chambers are meant for sleeping in, not living in throughout the day; consequently it is not of vital importance to have them as well lighted as an ordinary day room. Owing to the difficulty of making sure that they are hermetically sealed the usual practice is to have only one window in the room in which the chamber has been erected. How much sunlight was there in the allergen-free chamber in which the attempt to grow plants was made? Without details as to these and many other questions that I could suggest themselves to a practical gardener, it is impossible to form a judgement as to the correctness or the statement that cacti alone can be grown in allergen-free chambers. The clinic in Leiden is in an improvised building over-hung by trees, and I should regard it as anything but a suitable place for experiments on the growth of plants in allergen-free chambers.

The most valuable of Professor Storm van Leeuwen's statistics as to the benefit of allergen-free chambers in the treatment of asthma is based, not on the temporary freedom from attacks in asthmatics admitted to his clinic, but on the continued freedom from attacks in patients who have been sleeping in allergen-free chambers erected in their own homes. Professor Storm van Leeuwen regards

the allergen-free chamber a treatment as his most important contribution to the treatment of asthma, and from two results that I saw in the clinic at Leiden I entirely agree with him.

I feel very strongly on the subject of the treatment of asthma in England. I have recently been absent from my practice for eight months, owing to "asthma of the continuous type," which commenced at the age of 55 after my first attack of bronchitis. In spite of treatment by some of the most distinguished men in Harley Street, nasal cauterization, irrigation of my antrum, change of climate to various places abroad, including Biskra in Algeria, I became worse instead of better. It is entirely due to the results of the investigations of Professor Storm van Leeuwen during the past eight years that I have gradually improved till I am now able to undertake full duty, and hope, if I can find an English firm enterprising enough to erect an allergen-free chamber in my own house, to be absolutely free from asthmatic symptoms.

Whatever we may say to the contrary it is a fact that it is the practice in England to regard asthma as a pulmonary neurosis, hopeless from the point of view of treatment except by a change of climate. So long as we maintain this attitude, so long will we lag behind men like Storm van Leeuwen, who are earnestly and scientifically investigating causes and searching after possible methods of treatment of this incapacitating disease—I am, etc.,

Verbury Drive, Sept. 14th.

D. KENVET, M.D.

Sir,—In your leading article on "A treatment for asthma" (August 27th, p. 355) you kindly mention my name, but suggest that there are difficulties in harmonizing my work with that of Professor Storm van Leeuwen, particularly with regard to the use of feather and kapok bedding.

As you state, I believe most firmly in the value of the dermal reactions, and cannot do otherwise after seeing the scores of patients who have lost their asthma entirely by avoiding these proteins to which they are proved sensitive.

Where van Leeuwen uses the individual moulds I have obtained specimens of dust from patients' own houses and if they gave reactions to such dusts I have made suitable dilutions and desensitized the patient to the dust. Further, when Professor van Leeuwen was lecturing at the Royal Society of Medicine in 1924 I spoke and passed round culture tubes full of moulds showing that house dust consists chiefly of mould spores. The fact that Professor van Leeuwen has discovered that patients may be sensitive to individual moulds is extremely interesting and constitutes a valuable addition to the long list of proteins to which patients may be sensitive, but I do not think these moulds take the place of the other proteins. It is not yet proved, I believe, whether the spores of these moulds floating about in the air or some substance broken off from the proteins on which the moulds are growing, that constitute these air-borne allergens.

In my opinion patients may be sensitive either to feather or kapok or moulds as present in house dust, or to any one or more of these, and I hold that every case of asthma should be efficiently tested to every protein with which the patient comes in contact. I recently had the pleasure of seeing Dr. Rieckemann of New York, who entirely agrees with this preliminary investigation of every case of asthma. These reactions are extraordinarily specific. If a patient is sensitive to feathers alone he will be relieved of his asthma if put on kapok bedding. If kapok is in common use in Holland one would naturally expect many patients to become sensitive to it just as they do to bedding stuffed with straw, chaff, and hay in other places. If a patient is sensitive to house dust and moulds he will have trouble wherever the *house* moulds are to be found growing, including all forms of bedding that have been any time in use.

There are many intermediate stages and factors at work by which the proteins eventually bring about an attack of asthma, and there may well be other influences stopping the asthma at high altitudes besides an absence of dust and moulds. We may compare the amenorrhoea and other

menstrual disturbances that take place on the high table-lands of South Africa

I shall at once add these moulds to my test proteins and shall be extremely interested to watch the results, as I think Professor van Leeuwen's work will probably constitute a great advance in the treatment of asthma—I am, etc.,

FRANK COKE

London, W 1, Sept 10th

#### THERAPEUTIC ABORTION

SIR,—I am in complete agreement with many points in Mr Cook's letter in your JOURNAL of August 27th (p 368) as to the influence which starvation and dehydration have in the vomiting of pregnancy. I am also in agreement with the treatment as outlined by him, but I am glad to notice that it is "in the vast majority of cases" that this treatment is successful. The trouble is in the minority where the treatment fails.

Therapeutic abortion represents a confession of failure of that line of treatment, to sign the patient's death certificate is the complete confession of absolute failure—I am, etc.,

Edinburgh Aug 31st

H S DAVIDSON

#### FELO-DE-SE?

SIR,—I have recently attended a woman who died of peritonitis. In the belief that she was pregnant, and with the intention of producing an abortion, she had herself, ten days previous to her death, passed a foreign body into her uterus. As a matter of fact she was not pregnant, nor had she recently been so of this I am perfectly satisfied. I placed the whole facts before the coroner, who held an inquest without a jury and returned a verdict of "*felo-de-se*" I shall be obliged if you, or some reader whose forensic knowledge is more expert than mine, will inform me if this verdict was recording to law. According to my reading of the law it was not. The law is thus expressed "Every woman being with child, who, with intent to procure her own miscarriage, shall unlawfully, etc. and whosoever with intent to procure the miscarriage of any woman, whether she be or be not with child, shall unlawfully, etc." (Italics mine). The salient points in the case I quote are that the woman was not with child and that no other person was concerned in the act which caused her death—I am, etc.

Urmston Manchester Sept 3rd SIDNEY A WINSTANLEY

\*\* *Felo-de-se* as the name suggests, means one who feloniously commits self-murder, he being a felon with respect to himself. Dr Winstanley correctly quotes from Section 58 of the Offences against the Person Act of 1861, which constituted abortion a felony, and it will be seen that a distinction has been drawn between the case of a person who endeavours to procure abortion upon herself and the case of a third party who attempts to procure abortion upon another, and that in the case of the former an essential element is that the person charged should be with child. In the case of Regina v. Whitchurch, which was decided in 1890 it was held by Lord Coleridge, C.J., that a woman who was not with child could be convicted of a conspiracy with a third person to procure abortion, though if she stood alone she could not be guilty of the intended offence having regard to the wording of Section 58 before referred to. This is the nearest we can find to a direct decision upon this point, though the wording of the Statute is so clear that a definite ruling would hardly be expected as the prosecution of a woman who had either used an instrument or taken a noxious drug to procure abortion would not be likely to succeed unless she was in fact with child. From this it follows that the woman was not in fact guilty of a felonious act in making use of the means in question, as she was mistaken in her belief that she was with child. The coroner, therefore, would appear to have been technically incorrect in returning a verdict of "*felo-de-se*", she was not a felon towards herself as it could not be described as self-murder, the essential elements of murder being absent.

#### DRIED COMPLEMENT IN THE TROPICS

SIR,—In some tropical areas guinea-pigs are troublesome to breed and supplies difficult to obtain. Dried complement, if active, would be invaluable to the pathologist working in such regions. For some time past a preparation has been available and during last April a small quantity from a German source was received by Dr W. Fletcher, the director of the Institute for Medical Research, Federated Malay States, who handed it to me for testing.

The material was packed in sealed glass ampoules, each containing 0.1 gram. A solution of this quantity in nine times its weight of distilled water was claimed by the manufacturers to result in a solution equivalent to the original guinea pig's serum. The contents of three ampoules was taken up in 2.7 c.c.m. of water, but the resulting solution was, however, turbid and filtration was performed before proceeding to an evaluation test.

Estimation was carried out according to the technique of Tildes and McIntosh (Method 111, Medical Research Council Special Report Series No 14), except that the number of tubes in each row was increased to eight in order to allow of an increasing dosage to 0.5 c.c.m. of diluted complement. (The dilutions employed were 1/24 in the no antigen row and 1/85 in the antigen row.)

Incubation for fifteen minutes resulted in partial hemolysis only in the last tube. After an hour the corpuscles in the tube containing 0.5 c.c.m. of diluted complement were completely lysed, but hemolysis was still incomplete in the 0.45 c.c.m. tube. A control with local guinea pig's serum showed complete hemolysis in fifteen minutes with 0.15 c.c.m. of a similar dilution.

Sufficient complement for the usual Wassermann test (25 M.H.D.) would thus be contained in 0.5 c.c.m. of a 1/10 dilution of serum reconstituted from the dried material. Such a low concentration of fresh guinea pig's serum should not be employed for the Wassermann reaction, because the presence of a large quantity of serum during the test is likely to lead to fallacious results. If the sample tested was a representative one it is thought that dried guinea-pig's complement cannot be of value in tropical laboratories until the loss of complement, which occurs in proportion, has been considerably reduced by improvements in the drying process—I am, etc.,

A. NEAVE KINGSBURY, M.B., B.S.

#### SINUSITIS

SIR,—In your issue for June 4th (p 1004) I read an article by Dr Leonard Mickey on sinusitis in children. A few years ago I made some special observations on sinusitis in patients attending my medical clinic, and in a series of 391 consecutive cases I found 26.5 per cent had definite evidence of sinusitis. This was rather staggering. This condition is the cause of endless amount of disease, as it is a focal infection, and allows of the entrance of organisms to the blood stream, as does any other focal infection. It has been obviously overlooked in the past as a source of disease. This is very much so in gonorrhoea associated with exophthalmos. One very important factor I would like to emphasize is the finding of multiple infections, infected tonsils, sinusitis, and proctocolitis. This is so common that one is almost forced to the conclusion that the same organisms are responsible for all. I think tonsils are infected at a very early age from the parents, dental caries follows with adenoids and nasal infection, and later proctocolitis. Disease of any organ or tissue is possible from this source, but especially lobar pneumonia and chronic bronchitis with or without asthma. I have not, since I have been looking for it, been able to find a case of bronchitis or asthma without sinusitis, and I have not failed to clear up or greatly mitigate even cases of asthma. All the drainage from these infected sinuses passes down the chain of glands in the posterior angle of the neck into the mediastinal glands at the bifurcation of the trachea. The infection gradually spreads along the bronchi, giving the characteristic lobar thickening which is so often suspected of being tuberculous. The diagnosis of sinusitis is really very simple. The mere presence of a yellow post-nasal discharge unassociated with definite cold is absolute evidence. It may be intermittent or more or less constant. Headaches are almost always present except in pure nasal cases. Sinusitis is the cause of at

least 90 per cent of headaches with which I am afflicted. In the treatment of this very widespread disability no very fortunate have almost a specific in the action of colloidal manganese. My percentage of cures has been 90 per cent in the general run of cases, but in purely neural cases only 50 per cent. Where there is marked polypoid degeneration or low grade involvement of bone I have known nothing but time to give any good results.

Sinusitis in children is far more common than is suspected. All children with chronic running noses have sinusitis. In dealing with them cure can be obtained by giving them a quarter of a grain of potassium permanganate twice a day a quarter of an hour before morning and evening meals in a pill. I discarded vaccines five years ago as very unsatisfactory—I am, etc.,

SYDNEY PERK, M.R.C.S., L.R.C.P.

Melbourne Victoria July 20th

### TREATMENT OF GONORRHOEA

SIR—I have tried the treatment of gonorrhoea with hydrogen peroxide advocated by Dr Cock (August 15th p. 267) on many occasions, but with doubtful results. If injections are preferred or for private reasons have to be used, I find the old fashioned and generally discarded zinc salts as good as any, especially the sulphocarbolate. I have tried most of the new silver preparations from protargol onwards, but have not been much impressed by them. Concerning irrigation, I think that the chief action is mechanical, and due to simple lavage. The gonococcal action of any drug used in this way must be slight for the drug is not long enough in contact with the gonococci to produce much effect. Potassium permanganate is certainly one of the best preparations to use because, in weak dilution, it is harmless to the urethra. I conclude with a word of warning against the 'spraying up process' with various practised chiefly, I believe, in America. I have had cases treated by others in this way with disastrous results. The only way to abort gonorrhoea is to catch the gonococcus early (within twelve hours of first appearance of discharge) and treat by injections of any gonococcal drug preferred—I am, etc.,

### POOR LAW MEDICAL SERVICE

SIR,—After perusal of this year's Educational Survey of the Journal I observe that among the public services offering a medical career, there is no mention of Poor Law as being in the field of consideration. I know that this service is much discredited by the recently qualified as offering a possible career and it appears to me that some remarks upon it should prove useful particularly in view of rapid advances in recent years and of the likelihood of further changes for the better.

In these days of professional overcrowding no avenue of medical interest and livelihood should be left unexplored. Poor Law offers as good a career as any other public service, provided one is forewarned of difficulties and dangers. London and the large provincial cities have to-day finely equipped hospitals and infirmaries under purely medical administration, offering possibilities which cannot be ignored. There are also a number of full-time non-residential or "district" appointments and a still larger number of part-time appointments forming most valuable adjuncts to general practice.

Taking the average case of the young man with one or two general hospital appointments behind him and little or no capital, Poor Law deserves his consideration with other services for the following reasons.

There are large numbers of posts as resident assistant medical officers in Poor Law hospitals and infirmaries at salaries from £200 to £450 with full keep, and sometimes extras as well. The duties are much the same as those of a house physician or house surgeon in a general hospital with the following advantages.

1. The larger salary makes it possible to save a little capital for entry into general practice, while having the opportunity

to observe a suitable opening, and at the same time serving a most valuable apprenticeship. A part-time appointment may also be available to augment practice or partnership.

2. There is ample time and material in most cases for preparation for the higher qualifications with introduction to consulting practice and paid consulting appointments.

3. An introduction to Poor Law as a permanent career. Medical superintendents of Poor Law are paid from £600 to £1,600 plus house light coal, etc. First assistant medical officers are paid from £400 to £700 plus the above allowances. There are also full-time non-resident district medical officers, drawing salaries from £600 to £1,100, frequently with car or other allowances.

There is but one type of Poor Law appointment which requires a word of warning. There are still Poor Law institutions where the bulk of the inhabitants are sick, septic or simple minded, which remain under the administrative control of a workhouse master with his wife as matron. Full-time resident medical appointments in such places are only worthy of consideration either as a very temporary stop-gap, or where it is ascertained that administrative changes are imminent, either by complete separation of the sick and infirm from the rest under medical administration, or by the erection of an entirely new hospital. No matter what the personalities of doctor and master may be, if the proportion of medical work is large—and it must be to necessitate a resident doctor—the lot of the doctor is an unenviable one. He finds himself taking a markedly second place to the master and matron (man and wife) in work which is essentially medical. This of course, is absurd. I am not attacking workhouse masters and matrons in their proper sphere, but the system which permits of their retention in institutions which have far outgrown their original status of workhouse. I have had personal experience of this in an institution containing many hundreds of sick and infirm out of a total of about a thousand. The place I have in mind is a training school for nurses, assists in the training of students, has some hundreds of operations annually, a consulting staff, a ray plant laboratory, etc. It was, and still is, under the control of a workhouse master and his wife as matron. The difficulties in such a place render the whole position *serio-comic*.

It appears to me that the best and worst of Poor Law as a possible career should receive some publicity. There is a marked and increasing tendency on the part of the newly qualified to weigh the full-time public appointment, particularly with house, etc., provided, security of tenure, and a pension in later years against the exigencies uncertainty and worry which beset the young beginner in general practice, unless he is provided with adequate capital for a secure start. The facilities which Poor Law can offer entitle it to its share of consideration with the other public services in the difficult task of reviewing possible careers. Looking at the question broadly it appears to me to be very doubtful whether any other public service can show any greater all round advantages. I am, etc.,

D. CYRIL THOMAS,

Medical Superintendent at Battle Infirmary  
Paling Park.

Stretton

\* Dr Cyril Thomas's letter enables us to repair an undersigned omission.

### ALCOHOL AND THE MOTOPIST

SIR—Muscular inco-ordination is stated to be one of the signs of drunkenness. Muscular inco-ordination may occur in a motorist who has taken no alcohol.

Recently I had occasion to drive well over 200 miles in the day. The first 30 miles were driven before lunch, the remaining 180 or more were driven straight off. I started at 4.30 p.m., and finished up between midnight and 1 a.m. The last 70 miles were driven in the dark over known roads with some rain during the last hour. I ate and washed while driving and stopped two or three times for adjustments and petrol. I had no alcohol whatever during the day—the previous night I had one glass of whisky on going to bed. I was in fit condition and had driven nearly 200 miles the previous day. I have rather high

myopia, but no night blindness. About 70 miles from home I stopped for petrol, and then noticed nothing amiss.

On arriving home and getting out of the car my legs felt wobbly, but that I put down to sitting so long. Having put the car away I had some cake and milk—no alcohol. Half an hour later, on going to bed I found my legs still somewhat erratic, so much so that I remarked to my daughter, who had accompanied me, that it was lucky I had not met the police or they would surely have thought me drunk. On lighting my candle I found that my hand was unsteady. I did not feel excessively tired. I slept well and was perfectly normal next morning.

It was the duration of the inco-ordination that struck me as unusual—upwards of half an hour. I did not attempt to sit up to see how long it would last—I am, etc.,

Woolley, Herefordshire, Aug. 29th

JOHN S. CLAPKE

### PREGNANCY AND GLYCOSURIA

SIR,—I read with interest Dr. Kean's memorandum on the subject of pregnancy and glycosuria, which appeared in the *BRITISH MEDICAL JOURNAL* of July 16th (p. 100). I fail to understand why the case referred to should not have been considered a possible case of lactosuria. The relationship between the appearance of the reducing substance in the urine and the presence of milk in the diet is significant. The subjective symptoms experienced by the patient coincident with the bouts of "glycosuria" are certainly unusual in true cases of diabetes mellitus—I am, etc.,

A. J. HARR, M.B., D.T.M.,  
West African Medical Service

Accra, Aug. 8th

### COURTESY CALLS

SIR,—Up to a few years ago it was the custom for a man settling in practice to call upon his neighbours. Since the war this custom seems almost entirely to have died out.

The advantages to both the old-established practitioner and the newcomer are so obvious that it is not necessary to take up your space by recapitulating them. It does, however, seem worth while to point out that in the publication designed for newly qualified men this ordinary piece of common courtesy and medical etiquette should be dwelt upon, and I therefore ask the hospitality of your columns—I am, etc.,

Liverpool, Aug. 27th

G. F. RAWDON SMITH

\*\* Adherence to this custom is strongly recommended in the *Handbook for Recently Qualified Medical Practitioners*, published by the British Medical Association. The paragraph relating to it is as follows:

27. A practitioner newly settled in a town or district—deputies, assistants, and holders of—excluded—should call upon his professional colleagues to whom this courtesy should be extended are, generally speaking, those with whom the newly arrived practitioner is likely to come into contact. The first visit may well be paid to the Chairman or Honorary Secretary of the B.M.A. Division in which the practitioner has come to commence practice.

### POISONING BY OIL OF EUCALYPTUS

SIR,—In the *BRITISH MEDICAL JOURNAL*, June 4th (p. 1005), Dr. Giblin reports a case of poisoning by eucalyptus (blue gum), and adds that he finds no textbook records.

In the *Australian Medical Gazette* of June 20th, 1914, there was an article by Dr. Burton Cleland (Government microbiologist) dealing with Australian poison plants, referring to eucalyptus he cites from the *BRITISH MEDICAL JOURNAL*, February 18th, 1911 a summary by Dr. Foggie of blue gum poisoning. In it a case of my own is mentioned—the death of a boy from the oil in 1914 in Tasmania, with post mortem results—I am, etc.,

Sydney, July 22nd.

ALFRED NEALE, M.D.

### Obituary.

WILLIAM THELWALL THOMAS, M.B.E., CH.M.,  
F.R.C.S.

Consulting Surgeon, Royal Infirmary, Liverpool Emeritus.  
Professor of Regional Surgery and Clinical Lecturer in  
Surgery, University of Liverpool.

We regret to announce the death, which took place with tragic suddenness at his residence in Alleton, Liverpool, on September 10th, of Mr. W. Thelwall Thomas, the distinguished surgeon. To the knowledge of some of his colleagues, Mr. Thelwall Thomas had been in indifferent health for some months, and he recently had the misfortune to lose his wife after a painful illness. But he stuck manfully to his work, and performed an operation, with his usual brilliance and attention to detail, on the morning of the day he died. The summons came to him as he would have wished, while he was still in harness.

William Thelwall Thomas was the son of the late John and Elizabeth Thomas of Liverpool, and was born in that city in 1865. Ambitions from his youth, and endowed with great mental vigour, he early decided to enter the medical profession and, after completing his school education at the Liverpool Institute, he proceeded to Glasgow and enrolled as a medical student. In the Royal Infirmary there he came under the influence of men who were carrying on the work in antiseptic surgery initiated by Lister. Part of his training he received in the Royal Infirmary and Medical School of his native city, and in 1886 he passed the examinations for the M.R.C.S. Eng. diploma, and in the same year took the Scottish triple qualification. Thereafter he filled resident posts on both the medical and surgical sides in the Liverpool Royal Infirmary, and subsequently acted for a time as assistant lecturer in anatomy at University College, Liverpool, being Holt Scholar in 1887. In 1890 he was admitted to the Fellowship of the Royal College of Surgeons of England. This opened the way for his admission to the surgical staff of the Liverpool Royal Infirmary, where he became assistant surgeon in 1892. His conspicuous abilities as a surgeon were at once recognized by his colleagues. He was a man of ready resource, a fine surgical diagnostician, and a brilliant operator, with a gift for attention to detail.

In due course, after sixteen years, he was promoted to the full staff, and on his retirement two years ago, on reaching the age limit, he was appointed consulting surgeon. In addition to his hospital work and the demands of a very extensive surgical practice, which took him all over the north-west of England and far into the heart of Wales, he found time to fill the posts of professor of regional surgery and lecturer in surgery at the University of Liverpool. A man of general nature, who knew what it was to fight against unpropitious circumstances, he had a fine sympathy for his students and an excellent understanding of their difficulties. By them and by his house-surgeons he was much beloved. He had excellent didactic gifts, and could drive home the salient points in a difficult case with precision and certainty, so that students who followed his ward clinics had little difficulty in picking up an excellent knowledge of surgical practice, while those who worked with him in the theatre had a constant demonstration, not only of fine technical skill, but of conscientiousness of an unusually high order. In his university lectures he made great use of the pictorial method of imparting instruction, believing that mental impressions conveyed through the eyes were not only more valuable in surgery, but were also more readily grasped than impressions received through the ears. He presented an epidiascope to the University, and made constant use of it in his lectures.

Tradition says that Thelwall Thomas was the first surgeon to introduce a sterilizer into the Liverpool Royal Infirmary—in the shape of a five-shilling fish kettle. One of the first surgeons in Liverpool to put into full practice the antiseptic method, he soon proceeded to asepsis, and he was largely responsible for establishing a theatre technique of the highest order, which has been of incalculable benefit to those junior colleagues who have followed him. Endowed with a singularly receptive mind, he was no blind follower

of fashion. Up to date in all his methods, he refused to adopt new procedures simply because they were novel. He had a singular gift of appraising the value of a new procedure, and no operation was too daring to daunt him. But with him the safety and comfort of his patients came first. He was not prepared to subject them to new and comparatively untried surgical procedures if he was not convinced that the new method would render them and him better service than the old. He introduced several novel "gadgets"—for example, the detainer needle and black silkworm gut, and the large handled Spencer Wells forceps. He brought to a fine perfection his operation for herniorrhoids by suture over the face of the clamp. This operation has entirely displaced from hospital practice in Liverpool the old fashioned operation by clamp and enter.

And simultaneously with the Mayo in 1903, he introduced the transverse incision in the operation for umbilical hernia. In renal surgery he was responsible for the introduction of the double incision for stones occurring simultaneously in the kidney and distal end of the ureter, and, with the late Professor Benjamin Moore, he instituted an investigation into the chemical nature of renal calculi. This investigation altered completely our knowledge of this subject. All of the stones examined were proved to be of calcium oxalate. Previously they had been regarded as being composed of uric acid and urates.

Thelwall Thomas made many contributions to the literature of his subject, all of which were characterized by a simple directness and an entire absence of unnecessary detail. He was a practical man—not a word spinner. He contributed the article on surgical shock to the *Encyclopedia Medica* in 1903. His many writings are too numerous to mention in detail, but attention may be called to his report on "Fifty cases of hour-glass deformity of the colon," which was published in the *British Journal of Surgery* in 1921. To his numerous papers in the *Liverpool Medical-Chirurgical Journal*, and to his two addresses as president of the Liverpool Medical Institution on "The evolution of the voluntary hospital and its future" and on "The evolution of the surgeon and his training." He took a regular part in the discussions at the Liverpool Medical Institution and constantly exhibited interesting pathological specimens. His capacity for hard work was enormous. As an instance may be mentioned the fact that during the war he worked practically single-handed on the surgical side in the Liverpool Royal Infirmary, and the number of operations performed by him alone almost equalled the full complement under peace-time conditions.

He was with Mr. Paul, a pioneer in Liverpool in abdominal surgery and his careful technique, coupled with his executive ability, which was of the highest order, gave him the most excellent results. Honours came to him as he grew older. After the war he was made a member of the Order of the British Empire, and the affection felt for him by his colleagues and the confidence they had in his judgement were evinced by his election to the Council of the Royal College of Surgeons and the General Medical Council. On his retirement from his university and hospital posts he was pre-occupied by his colleagues and friends with his portrait in oils, reproduced on the next page.

When the British Medical Association held its Annual Meeting at Liverpool in 1912 Mr. Thelwall Thomas acted as joint local general secretary. He had been honorary secretary of the Section of Surgery in 1909 at Belfast and was president of the same Section in 1913 at Brighton.

Such, in brief, is an epitome of the professional career of a distinguished surgeon. But Thelwall Thomas was much more than a merely brilliant operator. He was a man with a thou and one fine qualities of head and heart. From his boyhood he showed grit and perseverance. Alone by his own unaided efforts he leaved out his career. He had no powerful influences to aid him, nothing but his own fine courage and his own great gifts. In his youth he led a hard struggle, but the memory of it did not embitter him, but rather made him more sympathetic to young men in like cases. Gentle by disposition and generous in heart he won and kept his friends. He was never jealous of his junior colleague. He was ever ready to lend them help from his large experience and to encourage them in every-

thing worthy they endeavoured to achieve. But he did not suffer fools gladly, though his judgements were charitable. He tested his men out. If they were true metal he took them to his heart and once admitted to that sanctuary it was not by any will of his that they left it. He rendered innumerable kindnesses to colleagues, he was generous without ostentation, and he was constantly doing little "acts of service and of love" that none but the recipients ever knew of. He was gifted with a fine sense of humour, he had the Celtic sense of the dramatic, and he could tell an excellent story.

In 1892 he married Anabel, daughter of the late Alexander Spence of Houth, Aberdeenshire. As already stated she predeceased him about two months ago. They had no children.

#### PREVIOUS PUBLICATIONS

We have received the following appreciations of Mr. Thelwall Thomas's work and character from Sir Robert Jones Bt., Sir James Barr who was President of the British Medical Association during the Annual Meeting at Liverpool in 1912, Mr. C. Thurstan Holland, lecturer in radiology in the University of Liverpool, Mr. F. T. Paul, consulting surgeon to the Liverpool Royal Infirmary, and Mr. R. I. Kelly, professor of surgery in the University of Liverpool.

#### SIR ROBERT JONES writes

The passing of Thelwall Thomas is a great loss to surgery, a painful shock to his friends and has cast a deep gloom over his native city. He was a surgeon who, from earliest days, earned the respect of his profession and the warm affection of his colleagues and his friends. He was marked out from the beginning, as possessing qualifications which made not merely for success, but pre-eminence. Not only a brilliant but an industrious student, he displayed a critical and well balanced mind, with that uncommon quality—a sense of proportion. His academic successes were constant and conspicuous. But what a wilderness of brilliant students we have known who have fallen by the way, whose early promise never fructuated—their energies blasted by the cold wind of lethargy and inaction. Thomas earned his reputation because he was an earnest student all his life. I remember him in his early days at his humble rooms in Mount Street always at work, cutting sections, elaborating notes, clearing cases—never for one moment idle. How rare it was in those days to be disturbed by a patient—the gods protected him. Would that the gods always protected men of promise from the tragedy of early success. Thomas realized what all students should realize, that undergraduate study is an aim and not only an achievement. It is the earnest carefully welded and fitted to prepare for the battle of life. As a graduate he worked conscientiously and long hours. He loved to work. Even in those days he realized his destiny and like a good labourer he ploughed his furrow straight. He knew no short cut to success. His path was not made easy for him. He had no professional influence to place him in positions of vantage. He owed his enviable reputation solely to his gifts of intellect and, what is equally important, character. In the true and highest sense he was a self-made surgeon. Every successive post he held was an inevitable appointment in each he more than justified his selection. Thelwall Thomas had another great asset—he had faith in his future. He steadfastly refused to be deflected from the career he had planned. I remember in the years of early struggle a very tempting offer was made to him to become lecturer in anatomy at one of our large medical schools. He refused the post when its acceptance would have immensely improved both his financial and academic status. No! he determined to become a great surgeon and to live and practise in his native town. When a man has attained to greatness he is apt to forget the early struggle and the bitter disappointments, and to speak instead of golden opportunities. The not abiding reputation is founded on triumph or obstacle. Thomas realized that each victory makes us stronger for the fight to come. "What credit to be dropped on Fortune's Hill the merit to climb it."

In Thomas's early days surgical posts were very few, and

a very apprenticeship had to be served before even minor official rank was obtained. Spade work was not merely a figure of speech, it was well-nigh exhausting. He had to prepare lectures for his seniors, diagrams for teaching, grind students for their examinations, and in those days it was not always that the sweet spirit of generosity is lavished by the master upon his slave. Let us hope that this old oppressive and suppressive atmosphere has been dispelled, and has passed for ever from amongst us, and that those who have attained high position and influence will remember their own early days, and in remembering make the path easier for those who follow them. Who can deny, however, that in Thomas's case the hard and strenuous path he so cheerfully traversed made his progress so irresistible and his position so unassailable? But we have not all the inflexible determination, the will to succeed, or the philosophic appreciation of the stimulus of failure.

Once given position and responsibility Thomas's rapid advance was assured. He was a great asset to hospital and to university. No more devoted teacher could be found, no more conscientious hospital surgeon. Many a time when we have been at a quiet dinner he has dropped his knife and fork with dramatic suddenness to answer an emergency hospital call. Even in his early days his technique was reproachable, and his manual dexterity a source of affectionate envy. He was a really great operator—bold but never reckless, rapid but never hurried, equally at his ease in zones of danger as in safe and simple ones. He inspired confidence and transformed an intricate operation into an artistic spectacle. When shall we ever see again a calculus which has lost its way in the meter so impressingly removed? He was one of a very few surgeons who covered with equal facility the operative field in all departments of general surgery. When we read his interesting contributions we feel they are far too few. That brain of his contained information which would have been a great gift to the surgical world. Thomas was great, not alone because he was a skilful operator, but because he had what we may call a true surgical instinct. He possessed not only the highest qualities of surgical technique, but that sound judgement so essential to the best interests of those entrusted to his care.

Only two months ago his wife, to whom he was passionately attached, died after a prolonged and painful illness. His agony was pathetic, and there can be no doubt he died of a broken heart. A man of sterling integrity and transparent honesty has crossed over, leaving only sweet memories behind.

SIR JAMES BARR writes

By the untimely death of Mr. W. Thelwall Thomas Liverpool has lost a very brilliant surgeon and a worthy citizen—a man who was held in high esteem by the medical profession and the public. His generous professional acts endeared him to a large number of the poor and needy, while he was ever ready to help his professional brethren in their difficulties.

He was the most dexterous operator which Liverpool has had since the days of Mr. Edward Bickersteth. As with Bickersteth, so with Thelwall Thomas when an operation was decided on there was no hesitation about the methods, every detail was carried out with rapid decision, a steady hand, and unerring judgement.

Thomas was alwaysaverse to prolonged anaesthesia, and the only time he was apt to become impatient was when the anaesthetic was imperfectly administered. He was not only a brilliant operator, but he was also an excellent diagnostician, and never operated for the sake of operating or of earning a fee. The number of exploratory operations performed by Thomas were few and far between. A short time ago he was requested to do such an operation in a case of jaundice. He refused, saying it was time the man had jaundice, but behind that there was advanced carcinoma of the head of the pancreas, and he could not live more than three months. All that could be done was to render the patient comfortable and treat symptoms as they arose. An operation would be wholly unjustifiable; it would not be surgery. The friends were not satisfied that everything had been done, another surgeon was called in who operated, and the patient was dead within six weeks.

W. Thelwall Thomas 1925

Thomas took a warm interest in the work of the British Medical Association, though he never had time to waste over its medico-political aspects. The great success of the Annual Meeting in Liverpool in 1912 was in no small measure due to his indefatigable energy as general secretary. Everyone connected with the meeting will readily remember how difficulties were smoothed over by his never-ending fund of good humour. I have had many opportunities of expressing my personal gratitude, and I now wish to place on record how much the Association is indebted to this versatile and genial surgeon.

He took a wide interest in the progress of medicine and in the advancement of our profession. A successful surgeon himself, he recognized that the chief struggles were in the lower walks of the profession, as he said to me, "There is always room at the top." He became a member of the Council of the Royal College of Surgeons, and on the death of Dr. Caton he was elected

to represent the Liverpool University on the General Medical Council—a better selection could not have been made.

Why or how he died I cannot wait to inquire, but I unhesitatingly say that there are many men who could, in the interests of the public, have been better spared. The death rate among medical men is much too high, they should set a good example to the public by preserving their own health and intellectual vigour.

After all it is not the length of life but its efficiency which should count and there are very few men who were more efficient in their day and generation than Thelwall Thomas. By his early death the loss to the public and the medical profession has been great and my wife and I feel that we have lost a dear personal friend.

Mr THURSTAN HOLLAND writes:

It is one of my privileges that I have been one of Thelwall Thomas's friends since the days when he first started as a pioneer of modern-day surgery in Liverpool—the first man who ever practised pure surgery in Liverpool, and declined any case which was not surgical. This, perhaps, is not generally known but it is nevertheless quite accurate. There was no surgeon in Liverpool before his days who entirely restricted his practice to surgical patients. In this respect Thomas showed one of his great characteristics—his capacity to vision the future. It is not my right to speak about him as a surgeon—that must be left to his surgical colleagues—but I can speak of him as a friend and as a member of the same hospital staff. In the early days of my connection with the Liverpool Royal Infirmary I was thrown very intimately into Thomas's work. The rare diagnosis of kidney stones was beginning and was interesting me. Whatever success I attained in this direction was very largely influenced by Thomas. He saw at once what could be accomplished by a man—far more than I did—and his encouragement and loyal support and help were ungrudgingly given. And so it was ever. Thelwall Thomas always gave his support to, and went out of his way to encourage, anyone—student or otherwise—who promised in any way to advance the science of surgery. He was a great surgeon, a great medical man, confident in himself, he inspired confidence in his patients, and his consideration for his patients was wonderful.

In his home life he was ideal, and probably a more devoted husband there never was. The last year of his life was saddened by the illness of his wife and the strain of this must have been at times almost insupportable. No doubt this strain told on him and hastened the end but one never heard a word of complaint. He went out quietly sitting in a chair and reading a book without pain and uncomplainingly—just the end he would have desired. His friends will miss him.

Mr F T PATEL writes:

The sudden death of Thelwall Thomas is a very sad shock to a large circle of friends to me a most unexpected shock. Few have known him longer than the writer of this short note for as far back as about 1878 he was 'walking the wards' of the Royal Infirmary when I was resident medical officer and surgical tutor. From the first contact with Thomas one recognized that he was a youth of exceptional intelligence, with an excellent capacity for work. Very early in his career he showed a special genius for surgery and while still quite young had his foot on the ladder up which he steadily climbed to be recognized as one of the most skilful and successful operators in the country.

Thelwall Thomas was not only skilful but kind and helpful to a degree and he gradually acquired a greater local appreciation than probably any Liverpool surgeon had previously obtained. He devoted himself wholeheartedly to his work, and did a great deal to advance the practice of surgery, especially by a very sound example. He was always up to date and a good judge of any real improvement which he would rapidly assimilate and make use of. Though he worked so hard and so regularly he took good holidays but unfortunately he had no hobbies outside his profession. If he had, and they had drawn him

sometimes from his work, we might have had the pleasure of his friendship and the value of his skilful help for many years yet but he was always absolutely devoted to his work, and nothing took him away from it but the regulation holidays which I believe he imposed on himself as a duty to health. Thomas of course held all the offices, practical and professorial, that he desired, and was esteemed, as he thoroughly deserved to be, in all. It is a sad thing for one so many years older, and never having imagined such a possibility till now, to be asked to write a line of appreciation for a man whom he has known and been in touch with as teacher, colleague, and friend for fifty years. The appreciation is best expressed in the profound sense of loss which will certainly be universally experienced by the profession and the public of Liverpool and a very wide surrounding district.

Professor R E KELLY writes:

The shock of Mr Thelwall Thomas's tragically sudden death rather overpowers a just appreciation of his life. Grief at his departure numbs all other feelings for we have lost in him a true friend as well as a great surgeon. And yet his death came as he would have wished—the sudden call faced with that courage which was the keynote of his character.

In the nineties, when he was assistant surgeon at the Royal Infirmary, it required courage to explore the cerebellum, to excise ribs to tackle exophthalmic goitres, ureteral stones and lung abscesses. Yet Thomas did all these operations comparatively early in his career. His observation was acute, his decision rapid and his work dexterous and complete. No detail was too small for his consideration. He had the capacity for seeing all round a problem, and once his mind was made up he stuck to his convictions with great tenacity. He read extensively, and perhaps for this very reason he wrote comparatively little but a glance at his papers and discussions shows how far advanced he was in surgical thought.

He was a great teacher, and had always something new and interesting to impart while his enormous experience was ever at the service of others. I worked with him constantly for over twenty years, a period of utterly happy collaboration and friendship. Thomas's integrity and ideals will always remain an inspiration to those who knew him. Such there is no better memorial than this.

**WILLIAM JOSEPH TYSON, MD, FRCP, FRCS,**  
Honorary Physician and Chairman Royal Victoria  
Hospital Folkestone

Dr WILLIAM JOSEPH TYSON, a distinguished medical practitioner in Folkestone, died on September 5th at the age of 76. He received his medical education at Guy's Hospital, where he was later house-physician and resident obstetrician, and obtained the diplomas M.P.C.S., L.R.C.P. in 1874, and in 1876 the F.R.C.S. by examination. In 1879 he graduated M.B. of the University of Durham, proceeding M.D. two years later. He obtained the diploma M.R.C.P. Lond. in 1889 and in 1901 was elected a Fellow of the Royal College of Physicians. He was an original member of the Association of Physicians of Great Britain and Ireland and regularly attended its meetings. He was a justice of the peace for Kent and chairman of the Bench for the Elham Division.

Dr Tyson commenced practice in Folkestone in 1876, where his father had long been established, though he did not join him in partnership. He devoted himself from the first to obtaining a wide knowledge of general medicine so as to fit himself for the position of consultant. He represented the South Eastern Branch on the Council of the British Medical Association from 1897 to 1903 and was again a member of the Central Council from 1912 to 1915. He was secretary of the Section of Public Medicine at the Annual Meeting in 1885, and vice-president of the Section of Medicine in 1907. He had also been a member of the Council of the Clinical Society of London. Dr Tyson devoted himself to the interests of Folkestone Hospital for fifty years where, in addition to his duties as physician, he had charge of the ophthalmic department. He held the post of chairman of the hospital for a long period, and

as recently as last August received Prince Henry on the occasion of the opening of a new wing. His literary publications included *Notes and Thoughts from Practice*, which was reviewed in our issue of July 31st, 1909 (p. 269), and several papers in medical journals on pulmonary and surgical subjects. His last contribution, dedicated to his colleagues at the Royal Victoria Hospital, was noticed in our issue of March 26th, 1927 (p. 572).

A colleague writes: Among those who have adorned the ranks of general practitioners in our time few have attained to such a position in the regard of his own profession and that of the general public as did Dr. Tyson. The fullness of his knowledge, his well-garnered experience, his breadth of view, and the simple-mindedness of his aim, commanded and returned to the end the respect and affection of his medical colleagues. He was a devoted churchman and a prominent member of the House of Laity for the Diocese of Canterbury. His election to the Fellowship of the Royal College of Physicians was richly deserved as a recognition of his efforts in upholding on all occasions the dignity of his profession and in promoting the attainment of knowledge. He never seemed to grow old, preserving as he did his sense of humour, his interest in new movements, and his love of children. He had all the characteristics of a true sportsman, and was a cricketer till he was 60. He was a fair shot, even in his seventy-sixth year, and played a sound game of golf. Alert in his movements, he was also quick in his mental action, and consequently was a good debater and a valuable chairman. His true kindness of disposition, generous thought for those in distress, and transparent sincerity will be sadly missed by all who had the good fortune of his friendship.

#### EDGAR GEORGE BARNES, OBE, M.D.,

Pontac, Jersey

We regret to announce the death of Dr. E. G. Barnes, OBE, who formerly practised for many years at Eye in Suffolk. Edgar George Barnes was born at Starbroke, Suffolk, in December, 1848, and after private study entered St. George's Hospital. After taking the diplomas of M.R.C.S. and L.S.A. he graduated M.B. Lond. (with honours in obstetric medicine) in 1870, and proceeded M.D. three years later. At St. George's he held the posts of resident obstetric officer and assistant chloroformist.

During his forty-four years of medical practice in Suffolk he became known to many members of the profession, more especially in the Eastern Counties, and was for some years a prominent member of the British Medical Association. In 1899 he succeeded the late Dr. W. A. Elliston as a representative of the East Anglian Branch upon the Central Council and remained a member of Council until 1909. He also served for short periods on more than one of the central committees. During the Annual Meeting at Ipswich in 1900 he undertook the duties of joint honorary local secretary, and he was subsequently elected president of the East Anglian Branch. In addition to this work for the profession he took an active interest in the Medical Defence Union, holding the office of President from 1911 to 1913 while the Norwich Medico-Chirurgical Society, of which he was a past president, elected him an honorary member upon his retirement from practice. He was for many years medical officer of health for the borough of Eye and the Hartismere rural district, and was elected mayor of the borough in 1908.

He left Eye at the end of 1913 and the last twelve years of his life were spent at Pontac in Jersey. During the war he acted as County Director of the Jersey Red Cross Society, being awarded the OBE in 1920. He became an active member of the Societe Jerseyaise and served on its executive committee. He took a keen interest in the Jersey General Dispensary and other local institutions.

Dr. MICHAEL BURNLEY, who was associated with Dr. Barnes as joint honorary secretary of the East Anglian Branch, writes: Edgar Barnes was one of the best workers for the Association, and to him was due the great success of the Ipswich meeting, when Dr. Elliston was President. He was a splendid organizer.

We regret to record the death of Dr. PERCY ALLAN, a leading practitioner of Croydon. He will be greatly missed by his fellow practitioners, to whom he had endeared himself by his strong personality and genial manner. Arthur Percy Allan was born at Chislehurst in 1868, and after five years' study at Birkbeck College entered Guy's Hospital Medical School. He graduated M.B., B.S. Lond. in 1894, and in 1898, after holding the posts of clinical assistant and house-physician at Guy's, he proceeded to the M.D. degree. During a large part of his successful career as a general practitioner Dr. Allan acted as surgeon to the St. John Ambulance Association, and during the war he was medical officer in charge of Wallasefield Hospital, which served as an auxiliary to the 4th London General Hospital. His war services were recognized by the award of the Medaille du Roi Albert. Dr. Allan was a man of varied tastes, and his literary ability was shown in a number of contributions to our columns and those of other medical journals. He was long a member of the Croydon Division of the British Medical Association, and was at the time of his death vice-president of the Surrey Branch. He was one of the founders and the first president of the Croydon Medical Society, and for several years acted as its honorary secretary. It was largely due to his interest and efforts that the society reached the high position it now holds. Dr. Allan leaves a widow but no children.

## Medical News.

THE new winter session will open at the Middlesex Hospital Medical School on Tuesday, October 4th. The introductory address, entitled "The paths to the stars," will be delivered at 3 p.m. at the Queen's Hall by Mr. Victor Bonney, M.D., M.S., F.R.C.S., after which the prizes gained during the past year will be distributed by the Right Hon. Lord Justice Sargent. The annual dinner will be held the same evening at 7 for 7.30 p.m. at the Savoy Hotel (Embarkment entrance), with Mr. Somerville Hastings, M.S., F.R.C.S., in the chair. Dinner tickets (price 11s. 6d., exclusive of wine) may be obtained from the secretary of the Medical School.

THE inaugural address of the winter session of the Westminster Hospital Medical School will be delivered on Monday, October 3rd, at 3 p.m., by Dr. E. W. Anstey Walker, dean of the school of medicine of the University of Oxford. The annual dinner for past and present students will be held on Saturday, October 1st, at 7 p.m., in the Royal Adelaide Gallery, at Gatti's Restaurant; the chairman will be Dr. do Souza.

THE Fellowship of Medicine announces that a two weeks' course in general medicine, surgery, and the specialties will start at the Westminster Hospital on September 19th, on the same date the Royal National Orthopaedic Hospital begins a fortnight's course occupying the whole of each day. A course in endocrinology at the National Hospital for Diseases of the Heart from October 3rd to 15th which is strictly limited to 20. A three weeks' course at the Central London Throat, Nose, and Ear Hospital will also begin on October 3rd, and include two parts, which may be taken together or separately, the clinical part occupying the whole day, and a practical operative surgery class in the mornings, and also a personal endoscopy course. A course in ante-natal work will be held at the Royal Free Hospital by Professor Louisa McIlroy on Fridays, at 5 p.m., from October 7th to 28th, the course is strictly limited to 10. On Wednesdays, at 5.15 p.m., from October 12th to November 2nd, Dr. C. B. Heald will give lectures and demonstrations in electrotherapy. Other courses will be given at the Chelsea Hospital, the Royal Eye Hospital, the London School of Hygiene and Tropical Medicine, and the Paddington Green and Victoria Hospitals for Children. A two months' course in neurology at the National Hospital, Queen Square, starts on October 3rd, consisting of attendance at the afternoon clinics at the hospitals and certain special lectures. Copies of syllabuses and of the general course programmes may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

HEALTH WEEK will be celebrated from October 2nd to 8th in various parts of the country, lectures, demonstrations, and exhibitions will be arranged, and prizes for essays on "The health road to happiness" will be awarded to school children. Further information and suggestions for programmes may be obtained from the Secretary, Health Week Committee, 90, Buckingham Palace Road, S.W.1.

THE annual dinner of past and present students of University College Hospital London, will be held at the Hotel Cecil on Friday October 14th, at 7 p.m. Sir George Black or will be in the chair.

THE "John Hampton Halo" Research Laboratory of the Royal Dental Hospital of London will be opened on October 4th, at 4 p.m. by Sir Walter Fletcher M.D., F.R.S., who will also distribute the prizes to the students.

WOMEN students are now to be admitted to the Royal Veterinary College, Camden Town, for the complete course of instruction for the diploma of the Royal College of Veterinary Surgeons.

THE Sims Woolhead course of lectures in constructive health education arranged by the Medical Council of the People's League of Health will begin on Thursday October 15th at 6 p.m. in the lecture room of the Medical Society of London. Participants may be had from the honorary organizer of the league Miss Olga Nettersole, 12, Stratford Place, W.1.

THE British Institute of Philosophical Studies has arranged the following courses of lectures for next term: Professor Alexander, "Value"; Mr John Hobson, "Economics in relation to ethics"; Professor Leonard Russell, "The approach to philosophy"; the Director of Studies "Introduction to philosophy"; Dr William Brown, "Psychology". A full syllabus can be had from the Director of Studies, 88, Kingsway, W.C.2.

Dr TOM HARRIS B.Sc. M.R.C.V.S. of the Lister Institute of Preventive Medicine, London has been appointed to the Chair of Pathology at the Royal Veterinary College. He graduated in medicine at the University of Liverpool in 1924 and proceeded M.D. last year.

Dr ADAM WILSON, V.D. J.P. of Newcastle upon Tyne has been appointed a Deputy Lieutenant for the county of Northumberland.

An abridged form of *The British Pharmacopoeia* has been translated into Chinese by Dr C. L. hao, and has been published under the auspices of the London Chamber of Commerce and the British Chamber of Commerce Shanghai. It may be obtained from the London Chamber of Commerce, 1, Oxford Court E.C.4 price 6s.

THE *Revista Sud Americana de Endocrinologia Immunologia e Chimioterapia* offers three prizes for the best works in Spanish, Italian, French, German, English or Portuguese on endocrinology, immunology, or chemotherapy. Works that can be used for commercial purposes are excluded. The value of the first prize is 1,000 pesos (£26) and of the second and third 500 pesos each. The award will be made by a committee consisting of university professors and the editor of the *Revista* *Medicina* 1745 Buenos Aires to whom the works should be sent before September 30th.

THE Orlis prize of 100,000 francs of the Institut de France has been awarded to Dr Charles Nicolle Director of the Pasteur Institute of Tunis, for his work in acute infectious diseases, especially in connexion with typhus, measles, and Mediterranean fever.

THE Bureau of the Far East at Singapore reports that during the week ending August 6th there were 12 cases of plague, all fatal; 443 cases of cholera with 261 deaths, and 100 cases of small pox with 22 deaths.

MESSRS BAILLIÈRE TINDALL AND CO. announce for early publication a new and enlarged edition of Dr Nathan's *Pulmonary Tuberculosis its Etiology and Treatment*.

THE report of the Professional Classes Aid Council (251, Brompton Road S.W.3) for 1925-27 shows a steady appreciation of its work. The Council began as a war relief fund in 1914, and in the following six years it dealt with 12,000 applications for help. Distress among the professional classes did not end with the war and the obligation remains to aid those who suffer as much as any and make no part of their suffering. The applications prove that there is permanent need of the Council's work. Its policy is to avoid doing immediate help is given where necessary, but the endowment is to set professional men and women on their feet. A great part of its work is bridge building tidying over temporary difficulties and helping people to permanent work. A correspondent wrote "The Council appears to be a sort of superman institution overlapping the more than sixty societies who are named as given. I do not understand why the professional classes with their numerous societies do not look after their own members. The reality was that these societies do all they can but their funds are often diminished under conditions that cut some applicants off from help. Some assist only their own subscribers some only aid those with definite qualifications. There is no overlapping for there is intercommunication in regard to any particular case that it appears possible may be provided for by another society. There is co-operation. Its income last year was just over £3,000 of this £5,500 was spent in the assistance of cases, mainly by way of paying fees for education.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**.

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are under no obligation to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring **PEPPINTS** of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1 on receipt of proofs.

All communications with reference to **ADVERTISEMENTS** as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are **HOUSEHOLD 9561 9562 9563** and **9564** (internal exchange four lines).

**THE TELEGRAPHIC ADDRESSES** are  
**EDITOR** of the *British Medical Journal* **Antiology Westcent London**

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements etc.) **Articulate Westcent London**

**MEDICAL SECRETARY** **Medutera Westcent London**

The address of the Irish Office of the *British Medical Association* is 16 South Frederick Street Dublin (telegrams **Nautilus Dublin**) telephone 4737 (Dublin) and of the Scottish Office 6 Drimshough Gardens Edinburgh (telegrams **Associate Edinburgh**) telephone 4261 (Central).

## QUERIES AND ANSWERS.

### CONSULTING ROOM COUCHS

"COUCH" asks for information about consulting room couches not too fantastic in design.

The Medical Supply Association (167-185 Gray's Inn Road) has a couch of the kind the specimen we saw was in and was covered with brown pegamoid but it could be made in mahogany. It had an adjustable head or back rest which could be flat with the rest of the couch or raised at any angle. The cost was £10. A similar couch made by the Holborn Surgical Instrument Company (Thames Inn Holborn Circus) is of polished mahogany or walnut color with adjustable back rest and sliding tray. Its price with straight legs was £6 with cabriole legs 15s more. The same firm had a more expensive couch though not more pleasing in appearance, embolism, a three action movement. The price plain upholstered was £10 15s and button upholstered £11 10s. Messrs Mayer and Phelps (59-61, New Cavendish Street W.) have a consulting room couch with an adjustable end upholstered in pegamoid it can be made in birch stained mahogany oak or walnut from £6 10s. The price of a similar couch adjustable at both head and foot and with metal plate legs, crutches for litho omni position is £13 15s. We believe that all the firms mentioned are prepared to build a couch to any design to suit the other furniture of the room.

## LETTERS, NOTES, ETC.

### PELVILETIF

DR. J. G. M. MORONY TINDALL writes: Prof. or Monro Kerr states the obvious truth in saying, "the consideration of the foetal head the best pelvimeter and the embryo a modification of Miller's method of examination—lateral pressure on the foetal head do not move it into the pelvis then as in two fingers of the other hand and into the vagina estimating the degree of over-riding of the foetal head with the thumb of this hand. The only danger I have had is that if the finger is pushed far into the vagina—in the region of the sacral promontory—one need an abnormally long thumb to reach the top of the sacral promontory's pubis. I suggest therefore the following modification. The foetal head is pressed down as before with one hand the forefinger of the other hand is placed into the vagina against the symphysis and overlapping the thumb of this hand overlapping is a small relief for the thumb but this time the forefinger is placed below and in contact with the symphysis. Of course the other methods such as estimating the distance of the sacral promontory are tried as well. This method may be of course for all I know be well known but I have never seen it described or heard it mentioned.

## A PALATAL REFLEX

Dr. R. ANDERSON (Birmingham) records the case of a lad, aged 17, who complained of a clicking noise in his mouth occurring when he was unable to breathe through his nose owing to a cold. He could produce the same noise by pinching his nose. There was a rhythmic click, click 156 times a minute, which became slower with deep or rapid moving up and down. Anderson adds that he has never heard of

## DIPHTHERIA SIMULATING FOREIGN BODY IN THE THROAT

Dr. CHARLES J. ILLI L. AITKEN (Kilburnist, near Rotherham) writes: A woman applied to the casualty department complaining that she had swallowed a fishbone and that she was certain it had stuck in her throat. She was referred to the throat department, where it was found she was suffering from diphtheria in the larynx. This is the opposite to the case recorded in the *Epilepsy* of August 20th (p. 141).

## HERPES AND VARICELLA

Mr. J. E. RUDDLES, lately a student at the Livingstone College, Leyton, and now engaged in missionary work in Painsway, reports a case of the association of herpes with subsequent varicella. A typical unilateral herpes rash developed in an Indian, with the usual pain and symptoms, it ran the customary course and cleared up in ten days. A fortnight later the patient's child developed varicella with a typical rash and slight fever, and a week later his wife became affected. Four other mild sporadic cases occurred subsequently in people living in the next house. Mr. Ruddles adds that chicken pox is not endemic in the sparsely populated district concerned, nor is it otherwise epidemic at the present time.

Dr. F. W. BLAKE GREAVES (Annandale, New South Wales) sends notes of an instance of herpes and chicken pox occurring consecutively in mother and infant. Herpes appeared first in the mother (aged 28) on October 15th, 1926, the infant (aged 4 months) began to suffer from chicken pox on November 3rd 1926.

Dr. W. T. TAYLOR (Ballyclare, co. Antrim) notes that most of the cases recorded of the association of herpes and varicella the herpes preceded the chicken pox when there was direct contact. He has recently seen a case in which neither of these conditions existed. The patient (a woman), who has been confined to the house for ten years on account of paraplegia, was attacked by herpes zoster on July 1st. An outside helper comes in daily to help in lifting her out of bed, etc. This helper's son, aged 7 years (not a patient of Dr. Taylor's) had had chicken pox six days previously, but at no time could have been near the paraplegic. If there was any connexion between the two attacks it would appear, Dr. Taylor considers, infection must have been conveyed to the paraplegic patient from the boy by his mother.

Drs. C. EDR and A. K. JAMES (Calne, Wilts) write: While a large number of cases have been reported in the last few years showing the intimate relation between herpes and varicella, practically all have been instances of one disease being followed by the other after contact. The following case is of interest in that it exhibited simultaneous development of both diseases in one individual, bearing a close resemblance to two cases reported by the late Dr. Claude Ker (*Lancet*, 1920, ii 347). On June 28th a man, aged 39, consulted us and stated that four days previously he had pain in the right side of his chest, on the following day a "rash" developed in that situation. One day later he noticed spots on the trunk and arms. He was found to have typical herpes zoster of the fifth right dorsal nerve; the vesicles being especially marked in the region of the lateral and anterior cutaneous branches. Scattered over the trunk and arms typical vesicles of varicella were to be seen.

## ETIOLOGY OF RHEUMATIC INFECTION

Dr. IFENG N. CLOUGH (Bristol) wishes to support the suggestion of "C. M. H." (*Hong-Kong*) (*Journal* August 13th, p. 293) that the study of diseases prevalent in temperate climates might be greatly aided by noticing their incidence in tropical and sub-tropical climates. Does rickets really not occur in Hong Kong? She states that when working at the Holdsworth Memorial Hospital in Mysore City she was so struck by the extreme frequency of rickets among the out-patient children that she made observations on 200 children, selected at random, they were continued for two months or more, and the English sister in charge of out-patients undertook the clerical work. Dr. Clough had to leave India on account of health shortly after and the records were lost but she recalls that the points noted were age, religion, method of feeding, date of teething, walking, and closure of fontanelle, beading of ribs, presence of Harrison's sulcus. Roughly, one fifth of the patients were Mahomedan, nearly four fifths were Hindu, both these were of all classes. In Mysore City as in other parts of South India, parrah is rare among Brahmans and high caste Hindus. A small percentage of patients were Christian (Roman Catholic and Protestant), the Protestant section were the more prosperous but neither section was wealthy. Most children were breast fed. Of the bottle fed babies she believes she noted that every child showed marked symptoms the older children especially displaying, even signs late walking, late teething, and barrel shaped chest with well marked sulcus. Hand feeding was not a success in Mysore City. Some were fed on milk, others on patent foods. Any patent food could be obtained in the city and the sale of patent medicines was enormous. Out of 200 children 199 showed beading of the ribs. The one exception was the child of Eurasian parents, where the father was earning good wages. These observations

were made in a year when conditions were at their worst after the war, high food prices, shortage of housing and of employment. Mysore City is 2,500 ft. above sea level and the climate is subtropical. Dr. Clough never noticed the thermometer on the verandah register a higher temperature than 95° F. or lower than 60° F. The city was within a rain belt area of 30 in. to 50 in. a year. There were three months of hot weather, the rainy season was from June to October but rain might fall in any month. There was no cold season. Sanitation, on the whole, was good—certainly far ahead of most Indian cities. The notes were taken from January to March—that is during the end of the cool season and the first two months of the hot season.

## HAEMORRHAGE IN THE NEWLY BORN

Dr. R. D. ATTWOOD (Royston, Herts) writes: In view of the two cases of haemorrhage in the newly born recently recorded in the *British Medical Journal* the following is of interest. On July 29th I was called to a baby 2 days old and found that a considerable quantity of blood had been brought up, the amount was difficult to estimate, being, of course, on cloths, it was certainly over half a pint. The treatment adopted was the administration of saline by the rectum and the intramuscular injection of 1 gram doses of calcium chloride. Slight haemorrhage continued for a few days, but subsequently there was a complete recovery.

## TYPHOID FEVER IN MONTREAL

From March 1st to June 28th, 1927, there were notified in the city of Montreal 4,755 cases of typhoid fever with 453 deaths as against 37 cases with 11 deaths, 48 cases with 18 deaths and 44 cases with 21 deaths, for the period March 1st to June 30th of the years 1926, 1925, and 1924 respectively. It appears, therefore, that since the beginning of last March Montreal has suffered a severe epidemic of typhoid fever with a case incidence in proportion to population probably unknown in any other large city in the world within the present century. No evidence was obtained that either the city water supply or the city sewerage system was responsible. The disease was distributed over the greater part of the area of the city with much more concentration in proportion to population of some sections than in others. It was found soon after the beginning of the outbreak that a very large proportion of those infected had drunk milk from a certain dairy company, and that a very considerable proportion of the milk which entered and was distributed from the plant had escaped efficient pasteurization.

## SCHILLER'S DISEASES

Dr. ERIC EBSTEIN of Leipzig, who is the author of clinical studies of Goethe, Chamisso, Lotzbeine, Lessing, Newton, and others, has recently devoted attention to the pathological history of Friedrich von Schiller (*Forschungen und Fortschritte*, May 20th, 1927). The poet, as is well known, started life as an army surgeon, but the success of his romantic play, "The Robbers," made him quit medicine for literature. It is noteworthy that two years before the publication of his play Schiller had written three articles on medical subjects one of which, on the difference between inflammatory and putrid fever, contained the clinical history of his friend August von Hoven. Physically Schiller was of a delicate and asthenic constitution. At the age of 23 he had a severe attack of influenza, and in the following years during his residence in Mannheim, he suffered from malaria in which was then very prevalent in the Rhine district, where even now it is occasionally met with in the summer. This attack of malaria was severe and, in spite of quinine, he had several relapses. In 1787, at the age of 29, he first developed symptoms which may be regarded as manifestations of intestinal tuberculosis, from which he suffered until his death eighteen years later. During this period he contracted whooping cough from his children and was laid up for over six weeks. His so-called attack of cholera in 1797 must be regarded as one of the manifestations of intestinal tuberculosis while the "red" another attack in 1805 are interpreted as an indication of ileo-caecal tuberculous only known to his intimate friends and Korner from all others. Wilhelm von Humboldt states he carefully concealed them. Dr. Ebstein relates that the last word he uttered was "nephthia" by which he meant Hoffmann's drops, then much in vogue for the treatment of colicky pain.

THE "MEDICAL REGISTER." UNTRACTABLE PRACTITIONERS  
"STILL ON THE REGISTER" writes: While having every sympathy with the Registrar of the General Medical Council in the number of non-replies to his inquiries it does seem somewhat strange that such names as that of the late Professor Stirling and the still living Sir Thomas Smartt should be included. We are all fallible and many of us very casual, but I think that the *Medical Register* might be checked with the *Medical Directory* (which, after all, is really to most of us more important in a sense) and, where the address is unaltered, the benefit of the doubt of our present existence be given us.

## VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 132.

## ROUTINE EXAMINATION OF THE CEREBRO-SPINAL FLUID IN SYPHILIS

ITS VALUE IN REGARD TO MORE ACCURATE KNOWLEDGE, PROGNOSIS AND TREATMENT

BY

CLAUDE H. MILLS, M.R.C.S.

Surgeon St. Paul's Hospital for Genito-Urinary and Skin Diseases

To-day we know that dissemination of the organism takes place very rapidly after inoculation in syphilis. The first appreciation of this fact would appear to date from the realization that total excision of the early chancre does not abort the infection, as for instance, in the case of the "malignant pustule" in anthrax. More recent experimenters have proved the presence of spirochaemes in the neighbouring lymph glands in rabbits in but half an hour following the cutaneous infection, and further, others claim to have obtained the organism from the cerebro-spinal fluid in the primary stages of syphilis in man.

The pathologists have provided us with a combination of most sensitive and accurate tests which can be applied to the cerebro-spinal fluid by means of which we are enabled to detect the earliest evidence that the nervous has reached the central nervous system. Prior to this clinicians were dependent wholly upon the exhibition of signs and symptoms in a patient resulting from neural dysfunction—often unreliable—before such diagnosis could be arrived at.

Upon this early recognition of central nervous system involvement in syphilis depends so much with regard to subsequent management of the case and the prognosis from a neurological point of view. The examination of the cerebro-spinal fluid in syphilis, therefore, is imperative, and should be carried out as a routine in every up-to-date clinic.

In the earlier part of 1916 whilst in charge of the syphilis cases at Rochester Row Military Hospital it occurred to me that with so much material at hand there was a good opportunity to carry out an investigation upon the cerebro-spinal fluid in syphilis in general. It was thereupon decided in future to examine the cerebro-spinal fluid prior to treatment in every patient. This was done with the following results:

### Primary Syphilis

The number of cases of primary syphilis examined was 233. They comprised:

(a) Cases with negative blood Wassermann reaction	147
Number of these with pathological cerebro-spinal fluid	7=4.76%
(b) Cases with positive blood Wassermann reaction	135
Number of these with pathological cerebro-spinal fluid	18=13.23%
Total number of pathological cerebro-spinal fluids	25=8.83%

### Secondary Cases

The number of secondary cases examined was 768. They consisted of:

(a) Previously untreated cases	559
Number of these with pathological cerebro-spinal fluid	173=31.8%
(b) Cases previously treated showing relapse of blood Wassermann reaction within two years with no clinical sign	62
Number of these with pathological cerebro-spinal fluid	27=43.5%
(c) Previously treated cases exhibiting clinical relapses of a secondary nature	147
Number of these with pathological cerebro-spinal fluid	69=46.9%
Total number of pathological cerebro-spinal fluids	274=35.4%

If we add the primary and secondary cases together we have a total of 1,051 in which were found 299 abnormal cerebro-spinal fluids (28.35 per cent).

### Extragenital Infections

In view of the supposition that there is a high incidence of central nervous involvement following upon extragenital chancres, more especially with regard to those situated in close proximity to the brain, an analysis of the findings in these cases is given. With regard to the theory that direct invasion of the central nervous system might possibly take place by way of the perineural lymph

channel in these cases the distance to be traversed by the organism would be comparatively short.

The number of cases with extragenital infections examined was 35. The *Spirochaeta pallidum* was detected in every chancre.

Of 29 secondary cases (advanced) the cerebro-spinal fluid was affected in	3=10.3%
Of the total 35 cases the cerebro-spinal fluid was affected in	4=11.4%

Taking into consideration the advanced stage to which the infection has progressed prior to examination, as is the rule unfortunately with these cases, one certainly would be judging from this error that the percentage of changes in the cerebro-spinal fluid is below the average found with genital infections of the same duration.

### Tertiary Cases

The total number of tertiary cases examined was 463. They comprised:

(a) Cases exhibiting active gummatous lesion	330
Number of these with pathological cerebro-spinal fluid	106=32.1%
(b) Cases with positive blood Wassermann reaction in which no active gummatous process could be discovered	133
Number of these with pathological cerebro-spinal fluid	71=53.8%
Total number of pathological cerebro-spinal fluids	147=31.7%

### Congenital Syphilis

The total number of cases (adults) examined was 87, of which 23 (25.3 per cent) were found to have abnormal cerebro-spinal fluids. It must be pointed out that all these cases are from amongst men who had been passed for military service and therefore the figures only apply to such cases as had escaped or survived some of the grosser stigmas associated with the congenital type of infection. Their ages ranged from 18 to 45 years. As might be expected the large majority were cases of interstitial keratitis, of which there were 72 amongst which 14 (19.4 per cent) were found with cerebro-spinal fluid changes.

### Neurosyphilis

The neurological cases investigated numbered 166 and the effect of various types of treatment was estimated by frequent clinical and pathological examinations.

With the evidence provided by the foregoing investigation, so amply supported by the findings of others, there can be no longer any question as to the absolute necessity of routine examinations of the cerebro-spinal fluid at a stage of the infection in syphilis. That the first attendance of a patient at a clinic should be accompanied by a minimum of discomfort in order that an accurate diagnosis will be followed by a willing and regular attendance is central.

With this aim in view it might be urged that in the instance of the early case the performance of a lumbar puncture following upon scraping of the chancre, possible gland puncture, taking of the blood specimen for the Wassermann test, intravenous injection of arsenobenzol, deep subcutaneous or intramuscular injection of bismuth or mercury plus massage might be calculated to increase the incidence of treatment defaulters. Here the personification both in the surgeon and the patient, is a very important factor. In intelligent sympathy combined with gentle and careful technique in the former but seldom rare in engendering confidence and appreciation in the latter. It is wise to keep the patient in bed for the lumbar puncture and for the ensuing twelve hours under aspirin and bromide. Unfortunately there is known as yet no infallible measure of eliminating that "bingbear" the reactionary headache, we can only lessen its incidence. Happily it is of the rarest occurrence in patients with grossly pathological fluids, and these are the cases in which frequent repetitions of spinal puncture are necessary.

If a patient is to be excused a lumbar puncture it perhaps at the first attendance of the primary case this might be permitted but in such instances never should this examination be omitted at the termination of the initial course of treatment—that is to say, in the first interval following upon the first ten to twelve arsenobenzol injections and the supplementary mercury or bismuth treatment. The subsequent progress of the untreated primary case with a pathological fluid should receive special scrutiny in this respect and is one calling for somewhat more intensive early treatment than a similar case with a normal fluid at the onset. At all later stages of the infection, examination of the fluid should be insisted upon prior to drawing up the scheme of treatment.

A paper introducing a discussion in the Section of Venereal Diseases at the Annual Meeting of the British Medical Association, Edinburgh 1927.

	Blood Wassermann Reaction	Cerebro-spinal Fluid	Inferences
Type (a)	Negative	Normal	The infection is well under subjection and residual foci if any are inactive. Prognosis good.
Type (b)	Positive	Normal	Residual foci in general tissues as opposed to the parenchyma of the central nervous system but early vascular lesions are not excluded. Prognosis good.
Type (c)	Positive ++	Wassermann reaction ++ ++ ++ ++ or + - - - Cells 50 to 250 or more Globulin ++ Lancet luetic curve	Points to active meningeal involvement. Prolonged and intensive treatment to be resumed at once but commenced cautiously to avoid Herxheimer reaction nipping of cranial nerves haemorrhagic encephalitis etc. This is the type which in the absence of delay in follow-up treatment will develop neuro-recidives. Subsequent cerebro-spinal fluid examination after the meningo-vascular element is eradicated will reveal the presence of possible coexisting parenchymatous involvement though rare. With thorough treatment the prognosis is good.
Type (d)	Positive but may be occasionally negative	Wassermann reaction ++ ++ + - - - or + + + + Cells 10 to 50 Globulin ± or + Lancet paletic curve	Should be regarded as strongly suspicious of parenchymatous involvement of the central nervous system and repeated cerebro-spinal fluid examination at three monthly intervals whilst under continuous treatment is imperative combined with careful clinical neurological investigations. More especially the prognosis is bad if an initial examination of the cerebro-spinal fluid prior to treatment revealed early changes. Prognosis general paralysis of the insensate and tabes are frequent in this group.
Type (e)	Positive	Wassermann reaction ++ + - - - Cells 5 to 20 Globulin ± or absent Lancet luetic or nil	Suggests residual foci in general tissues plus meningeal vascular involvement of central nervous system—the meningeal factor slight or under subjection. Will probably show normal fluid after further treatment. In the absence of such a likely candidate for cerebral endarteritis (hemiplegia, hemianesthesia etc.)

In my opinion the most critical epoch in the career of a syphilitic is this period at the termination of the initial course of treatment, for, in the light of our present knowledge, not until now are we enabled to "grudge" with some degree of accuracy the "depth of penetration" of the invasion by its response to treatment. In fact, this first course of treatment should be regarded in the nature of a "therapeutic test," and should therefore be "standardized" to consist of the administration of not less than 4 grams of salvarsin (or the equivalent of neo-salvarsin) plus bismuth and mercury over a period not exceeding fourteen weeks.

It is now that in examination of the cerebro-spinal fluid, read in conjunction with the blood Wassermann reaction, affords such valuable information, and should be made six weeks after the cessation of the initial course of treatment, and prior to resumption. (During the first four weeks of this "test period" the patient is usually given iodides.) The accompanying table may be found useful as a rough guide as to the significance of certain types of fluids met with at this stage in regards diagnosis, prognosis, and future treatment.

*What importance should be placed upon these findings in the cerebro-spinal fluid in deciding upon the subsequent management of the case?*

#### Type (a)

Provided that sound treatment is continued for a minimum further two years, in the absence of any pathological findings it should yield 100 per cent cures. The cerebro-spinal fluid should be examined at the end of the first, second, third, and fifth years.

#### Type (b)

As above, excepting that the "two years" should date from the time that the blood Wassermann reaction was rendered negative. Several workers have noted that a normal fluid at this period is a very good omen that the central nervous system will not develop evidence of involvement subsequently.

Schmidt investigated in after-years, 155 cases in which at the initial examination the cerebro-spinal fluid was normal prior to treatment, or had been found to be negative five years after the termination of treatment. In those cases tested the cerebro-spinal fluid was found to be still negative. Wild and Marshall stated that in several thousand cases in which lumbar puncture was performed a positive fluid was found in only three cases which had previously been found negative. Moore and Kemp consider that the evidence gained by the repeated routine spinal punctures in a series of 54 patients justifies a general statement that in early syphilis, if the cerebro-spinal fluid is normal after six months' treatment, the patient will not develop clinical neurosyphilis, nor a positive fluid unless a second dissemination of the organism is permitted to

take place, as evidenced clinically by recurrent secondary syphilides or a blood Wassermann relapse. Fouldes has stated that if the cerebro-spinal fluid is once found to be normal after treatment the probability is that the central nervous system will not be affected subsequently.

#### Type (c)

Changes as gross as those to be found only six weeks after cessation of arsenobenzol therapy would indicate severe meningeal invasion such as is more likely to be experienced after a longer rest from treatment. Moore and Kemp found the average time interval between the day of the last treatment and the onset of neuro-recidives in 27 such cases to be 21 months. Kemp and Chesney reported a case in which syphilitic meningitis of the neuro-recidive type developed four months after cessation of treatment, which had been commenced in the primary sero-negative stage. Three cubic centimetres of the cerebro-spinal fluid (which was positive to all tests) was inoculated into a rabbit's testicle. Approximately sixty-eight days later the animal developed an orchitis, in which numerous *Sp. pallida* were demonstrated fourteen days afterwards.

Such relapses were seen far more frequently in the early days of arsenobenzol therapy when the dosage was what we know now to be very inadequate—in fact dangerous—in that it was usually sufficient to inhibit the natural output of antibody by effecting a temporary suppression of spirochaemes. Thus when residual "nests" of the organism awoke to renewed activity—whether situated in the meninges or elsewhere—they did so, as it were, upon virgin soil, just as in the secondary stage of the untreated case, in fact it seems possible that a second dissemination could take place. It is by means of the early recognition of meningeal involvement by routine examination of the cerebro-spinal fluid during this pre-symptomatic period that we are enabled entirely to prevent, by immediate resumption of treatment, the development of such evidences of gross inefficiency as cranial palsies, etc. In the type under discussion it is certain that the "protective mechanism" of the central nervous system has been called into action, and it is only by subsequent examination of the cerebro-spinal fluid, after the meningo-vascular element has been cleared up by treatment, that its efficacy in protecting the parenchyma is revealed.

The prognosis, assuming that the condition is recognized in the asymptomatic stage whereby prompt and intensive treatment can be cautiously resumed, is good. If irreparable damage has been caused prior to the resumption of treatment the processes can be arrested with perseverance, but permanent dysfunction will persist in proportion to the extent of neural destruction. Routine examination of the cerebro-spinal fluid should render impossible the development of any such disabilities. It is recognized by all that the case which relapses once is very prone to exhibit subsequent recurrences.

## Type (1)

The importance of the early recognition of this type cannot be overestimated as regards diagnosis, treatment and prognosis. It is in this group perhaps more than in any of the others that the findings at the initial pre-treatment examination of the cerebro-spinal fluid convey most. Should the first examination have revealed early changes which under the "test" course of treatment have progressed as indicated the presumptive evidence of parenchymatous involvement of the central nervous system is very strong.

With this evidence before us some workers go so far as to state that we are no longer justified in continuing treatment along the lines of the ordinarily accepted schemes of intravenous or deep-subcutaneous arsenobenzol therapy, whereby valuable time is allowed to elapse, during which the progress of the parenchymatous invasion is not materially checked. They urge that at once more drastic procedures should be employed. Bunker advocated the following four lines of therapy should the positive Wassermann reaction and paretic gold curve be present in the cerebro-spinal fluid after the initial course of treatment:

- 1 Intraspinal injections by Swift-His technique at short intervals
- 2 As above supplemented by intracerebral injections
- 3 Thorough trial of trypan-blue
- 4 Treatment with malaria

He feels that two weeks given over to malaria in these "pernicious" cases may be worth several months under the other schemes of treatment with which the malaria can be immediately supplemented. Kahl of the Vienna school advocates an earlier exhibition of the malarial treatment in those cases of syphilis with a distinct serological or cerebro-spinal fluid findings rather than waiting until a hitherto for the proclaimed tubercle or paretic. Any treatment which has been proved capable of sending normal the cerebro-spinal fluid in a general paretic should be given at this period to the type of case under discussion. Massive doses of silver salvarsan intravenously accompanied by sulfarsenal deep subcutaneous plus spinal drainage has been spoken well of by Harrison in this respect in an advanced paretic.

## Type (2)

Early recognition of the cases coming within this category is second in importance only to that of the preceding group because in the event of the immediate resumption of treatment which is hereby indicated the prognosis in the great majority is good. On the other hand in the absence of such resumption or where a protracted rest interval is followed by inadequate supplementary courses of treatment the clinical disaster resulting from endarteritis of the central nervous system are of an alarming nature. The "plegias" always leave in their wake a varying degree of permanent damage no matter how efficiently the case is treated after the onset of such. In the syphilitic who is willing to remain under prolonged observation during which the blood Wassermann reaction and cerebro-spinal fluid are tested at regular intervals endarteritis of the cerebral spinal or in fact any vessels should never be allowed to progress unperceived in the absence of treatment.

Possessed as we are today of modern improvements in specific therapy and the delicate tests for controlling the response of an infection to such the development of, say hemiplegia in a lues syphilitic is to be regarded as the fault of the doctor or the patient—perhaps both—but not the disease. The findings in the cerebro-spinal fluid as indicated in this group might equally well occur with an early mild meningeal involvement or one which has been partially cleared up by the initial course of treatment.

It matters nothing however whether it is the meninges or the vessels which are principally involved at this stage, what is of paramount importance is the immediate necessity for the resumption of treatment. Re-examination and comparison of the findings in the cerebro-spinal fluid after early follow-on course of treatment will provide most

valuable data in assessing the accessibility of the spirochaemes in a particular infection. Upon these findings everything will depend in deciding the subsequent management of the case.

## The Importance to be placed upon the Various Tests and their Significance

**Junge Colloidal Gold Reaction**—Although the results obtained from its employment are not recorded by me in the series of cases mentioned this test was used in all of the frankly neurological cases and subsequently to a less progress in the majority of those other cases in which a grossly pathological fluid was discovered at the first examination. The utmost care in the preparation of the colloidal gold solution and the cleansing of the glass utensils has a very important bearing upon the "readings" obtained with the test. From my clinical observations over the past ten years of the progress of a considerable number of neurosyphilitics I am firmly convinced that a strong paretic curve accompanied by a persistent positive Wassermann reaction in the cerebro-spinal fluid is to be regarded as of the gravest prognostic significance. Miller and his collaborators found, upon examining the cerebro-spinal fluid from 252 cases composed of paretics, tabetics and of cerebro-spinal syphilis that the Junge reaction was invariably positive when the Wassermann test was positive and in 4 cases was positive when the Wassermann test was negative. Wendt considers its sensitiveness one of the main advantages of the colloidal gold test in that it may indicate the necessity for further treatment when all other tests are negative. He also regards an early strongly paretic type of reaction in syphilis as an omen for a bad prognosis. Hunt believes that the gold test next to the cell count is the most important of the four main tests supplied by the cerebro-spinal fluid and in his experience has proved that most sensitive and delicate. It is both of diagnostic and prognostic value. It forecasts the future development of the disease more than any other laboratory measure. The gold curve he considers can be used as a guide and with its fit tendency to simulate the curve of paretic is the material treatment could be instituted.

**The Wassermann Reaction in the Cerebro-spinal Fluid**—It is infrequent to find a positive reaction in the cerebro-spinal fluid in the primary stages and then only with two volumes of fluid more rarely with one volume. In none of the primary case in my series did it occur with the smallest amount of fluid. In the secondary cases one more frequently meets with stronger reactions especially in the relapse cases. Amongst these the "meningo" or "neurocidive" cases in conjunction with a high cell count and excess of globulin the Wassermann test may show ++ throughout the four dilutions. It is in this type that the Wassermann reaction in the cerebro-spinal fluid is most easily influenced by treatment but may remain refractory with two volumes of fluid for a long time after the cells and globulin have disappeared. In later cerebral syphilis of the meningo-vascular type much the same conditions in the fluid commonly exist. Of all syphilitic conditions the Wassermann reaction is most certainly strongly positive in the cerebro-spinal fluid in general paresis and also the most difficult to influence by treatment. In tabes it is somewhat more responsive and especially is one liable to be too optimistic in the earlier part of treatment when the existing meningo-vascular element is being brought under subjection as evidenced by the decrease in cells and globulin and possibly the Wassermann reaction to a less degree. Eventually however a stage is reached when the Wassermann reaction remains rigidly positive with two volume and with one volume of fluid with the cells swinging between 5 and 15 per cmm. Such one feels to be representative of the true residual parenchymatous involvement. A persistent positive Wassermann reaction in the cerebro-spinal fluid after the initial course of treatment in the early, or in fact any stage of syphilis should always be regarded as an absolute indication for prolonged and intensive continuation treatment controlled by re-examinations of the cerebro-spinal fluid at regular intervals at which the

Lange test is never omitted. I regard a positive Wassermann in the cerebro-spinal fluid as an indication of the existence of spirochaemes within the central nervous system, and cannot accept Dujardin's theory that the Wassermann substance is not formed within the central nervous system, its presence in the cerebro-spinal fluid being dependent upon the permeability of the capillary walls to permit of its passage from the blood into the perivascular lymph spaces or not. We frequently meet with a positive Wassermann reaction in the cerebro-spinal fluid accompanied by a negative in the blood, a condition which can exist for many months and remain constant in spite of exhaustive spinal drainage up to 80 or 100 ccm twice weekly. Moreover, the organism has been proved to exist in the cerebro-spinal fluid, and interstitial and parenchymatous central nervous tissues.

#### Cells and Globulin

"There is never smoke without fire," and in syphilis the cells and globulin in the cerebro-spinal fluid might be regarded as fairly reliable indicators of the intensity of the inflammatory meningeal blaze, thus in syphilis a severe involvement of the meninges is responsible for a gross excess in each, as with other infections. An increase in cells of from 5 to 10 was the most frequent first change to appear in the cerebro-spinal fluid of the primary cases previously described, the excess in globulin coming next, with a positive Wassermann reaction in the comparison, and then usually accompanied by a pleocytosis. The detection, therefore, of an excess in cells or globulin in the cerebro-spinal fluid is invaluable in furnishing the first evidence of central nervous involvement in syphilis in order that treatment can be planned accordingly and its efficacy judged by subsequent examinations of the cerebro-spinal fluid. Some observers have found an invariable increase in pressure in fluids showing this early pleocytosis.

Should a cell count of, say, 8 to 15 be returned, after the initial course of treatment, as the only abnormality, I consider it to be an indication to push treatment, but would regard a solitary slight excess of globulin as of less importance, since it can persist over very long periods in cases which, by prolonged observation, have been proved subsequently to do well.

Since the methods are so simple it is better in the routine examination for globulin always to employ both the Pandy and Nonne-Apert methods, for, as Greenfield and Carmichael point out, whereas a trace of globulin might be detected by the one, a negative with the other test would prove it to be within the normal limit.

#### Some General Views Expressed by Various Investigators

O'Leary, Paul, and Nelson call attention to the fact that neurosyphilis may progress clinically in the presence of completely negative cerebro-spinal fluid findings. They found that continued treatment after the cerebro-spinal fluid has become negative is productive of 70 per cent of clinical benefit, and 45 per cent in those whose fluids returned to normal without treatment. They conclude that such investigations of the cerebro-spinal fluid plus clinical examinations should be made in all neurosyphilis whose fluids have become normal, with or without treatment.

Bunker asserts that the purely clinical differentiation between the meningo-vascular and parenchymatous forms of neurosyphilis not only often presents considerable difficulty, but is, in fact, sometimes quite impossible during life. It matters but little what label one may elect to apply—meningo-vascular or parenchymatous, mesodermal or ectodermal what, however, is of paramount importance is whether the treatment is proving efficient in a given case of neurosyphilis regardless of such label. This can only be judged by the definite and progressive influence exerted upon the positive findings in the cerebro-spinal fluid. This evidence cannot be obtained without repeated examination of the cerebro-spinal fluid as treatment progresses. A single examination of the cerebro-spinal fluid he regards as of about as much value as a single temperature reading in any acute infection. He points out how misleading and of what little value symptomatic amelioration may be in the absence of concomitant improvement in the cerebro-spinal fluid.

Fordyce pointed out that the signs and symptoms of involvement of the nervous system in the early months are sometimes absent or are so indefinite as to be easily overlooked. If lumbar puncture is limited to the cases with obstructive signs invariable during its result—a low-grade parenchymatous encephalitis, with slight or no meningeal involvement, may exist for years with indefinite symptoms impossible to classify or interpret without the aid of spinal fluid tests. The absence of the praeputic gold sol curve in the majority of cases definitely excludes paresis. Cerebral meningo-vascular syphilis and general paralysis may give identical findings in the cerebro-spinal fluid and present very similar clinical pictures. The persistence of a strongly positive Wassermann reaction in the high dilutions with a praeputic gold curve after intensive and prolonged treatment is the only practical way of differentiating these closely related clinical conditions. He and his co-worker (Rosen) had yet to detect a recurrence in an early case of neurosyphilis which had been discharged with a negative cerebro-spinal fluid after adequate treatment, or to observe a late infection of the fluid in one shown to be normal in the first two years of the disease. He considered that if the nervous system is not involved in the early period of the infection it is extremely improbable that it will be at a later date, vascular lesions and gummata being excepted. Certain types of neurosyphilis, including the purely vascular, the gumma unaccompanied by a meningitis, some unusual psychoses, and epilepsy of luetic origin, are often found with little or no change in the cerebro-spinal fluid. These exceptional conditions in no way alter the general rule that the cerebro-spinal fluid reflects the pathological process in the brain and cord.

Mott considered it probable that the cases in which the cerebro-spinal fluid remains positive after prolonged treatment are those which subsequently (average ten years after primary infection) develop tabes and general paresis. There is hardly any organic disease of the nervous system which may not be simulated by syphilitic disease, but, he added, it must be remembered that functional diseases may occur in syphilitic subjects. *Nemasthenia plus syphilophobia*, on account of the venereal disease propagandi, is frequently met with at the present time. (Another strong indication of the value of cerebro-spinal fluid examination.)

In a paper upon the diagnosis and treatment of neurosyphilis Hunt makes the following very sound observations: "The most successful diagnostician of all is he who has the clinical reports in his right hand, those from the laboratory in his left hand, and the patient in front of him." The reason for erroneous diagnosis and for unrecognized neurosyphilis is largely the fault of the physician, "it arises from his unwillingness to do a lumbar puncture." And again: "No neurological diagnosis should ever be made until syphilis has been eliminated by an examination of the cerebro-spinal fluid, and no diagnosis of neurosyphilis ought to be accepted until the cerebro-spinal fluid has been examined." In the vast majority of cases he considers that this one test will settle the question.

#### Conclusions

- 1 Routine examination of the cerebro-spinal fluid is absolutely essential in the management of syphilis.
- 2 The cerebro-spinal fluid furnishes the earliest and most accurate indications governing diagnosis, treatment, and prognosis.
- 3 In the primary stage it is an advantage, in the later stages imperative, to know the condition of the cerebro-spinal fluid prior to the commencement of treatment.
- 4 The cerebro-spinal fluid should be re-examined after a period not exceeding six weeks from the cessation of the initial course of treatment, such "standardized" course of treatment to be regarded in the nature of a "therapeutic test."
- 5 In the earlier cases this is the most critical period in the management of the infection, since it is now that the cerebro-spinal fluid might provide possibly the first and only evidence to indicate invasion of the central nervous system, and within broad limits the depth of such invasion when present.
- 6 The warning obtained from routine cerebro-spinal

fluid examination at this period should prevent entirely the subsequent development of neurological relapses, and their sequelae.

7 A positive Wassermann reaction in the cerebro-spinal fluid (especially if such existed prior to this initial course of treatment) accompanied by a parietic Jarisch curve is strong presumptive evidence of parenchymatous involvement of the central nervous system at this stage. Rigorous intensive schemes of treatment should be instituted forthwith for its eradication by which such valuable life may be saved.

8 In every early case treated at this subsequent examination of the cerebro-spinal fluid should be made, accompanied by the blood Wassermann test at the termination of the first, second third and fifth year. Continued treatment and subsequent management to be continued thereby.

9 After cases presenting a persistent positive blood Wassermann reaction no matter at what stage of the infection the patient first comes under observation should have the cerebro-spinal fluid investigated, accompanied by a careful neurological examination. The distinction between cerebral and spinal endarteritis would be indicated thereby and a timely prevention by adequate treatment.

10 A routine blood Wassermann test should be made upon every patient at all medical institutions irrespective of the nature of the complaint and when found to be positive an investigation of the cerebro spinal fluid should follow.

11 Once the cerebro-spinal fluid has been found to be pathological in a syphilitic case subsequent examination of the fluid is imperative for many years after it has been rendered normal.

12 Lueseritis are regular recurrences indicated in those cases which have once relapsed and in prodromal cases of neurosyphilis after the fluid has become normal. The old aphorism, "Once a neurosyphilitic always a neurosyphilitic," must never be regarded lightly.

13 Neurosyphilis—more especially of the cerebral type—can progress clinically in the presence of negative findings in the cerebro-spinal fluid, yet it can be much hastened by specific treatment. Much valuable time and labor is to be obtained from the stilled neural system during progress in such cases, and should always be utilized.

14 The earlier treatment is commenced in the detection of the disease the chance of preventing syphilitic involvement of the central nervous system, the earlier the termination of such, should it have occurred, the greater the possibility of preventing the invasion of the parenchyma.

15 No patient with a history of syphilis should be given mercury without an examination of the cerebro-spinal fluid.

#### DISCUSSION

Dr. R. R. RICHMOND (London) said that a balance had to be struck between positive pathological changes in the cerebro-spinal fluid and negative clinical findings. It was the initial six weeks' course of treatment where there were such pathological changes the patient should be treated for the rest of his or her life, or, at any rate, should be kept under periodic inspection. It might be a bad scheme for a patient in whom the cerebro-spinal fluid had become negative after having once been positive was safe after five years had elapsed, the arsenic must be in the negative for he might get tabes with an apparently normal cerebro-spinal fluid. It must be remembered that it was the business of the physician to treat human nature and not positive Wassermann reactions. Moreover, the remedies employed were poisonous and it was possible to overdo an antisyphilitic therapy. Severe headaches were liable to follow lumbar punctures, and one such might make a patient rebel against any further examination, hence it was important to take every precaution, one of the essentials being the use of a fine needle.

Dr. D. K. HENDERSON (Glasgow) thought that routine examination of the cerebro-spinal fluid was open to serious objection because in not a few cases the after-effects were serious. In his opinion it was essential that the patient should be kept in bed for at least twenty-four hours after

the puncture. The early diagnosis of parenchymatous syphilis was impossible, because patients with only the slightest clinical signs might present advanced pathological changes in the cerebro-spinal fluid. It often happened that the earliest cases and consequently the most promising turned out the most disappointing in treatment, while others who came under observation comparatively late did relatively well. There also occurred cases of tabes and general paralysis which showed no apparent pathological change in the cerebro-spinal fluid. He considered that no patient who had had general paralysis, even if supposed to be cured should ever be allowed to hold a position of responsibility.

Dr. J. C. GREENFIELD (London) described several tests for the cerebro spinal fluid in neurosyphilis and said that the Kahn test was very fairly comparable with the Wassermann test, but it was sometimes really positive when the latter was negative. The test of Bollz was almost specific for general paralysis. Other tests recommended were those of Haffa, which corresponded with Jarisch's test, and Winkler's colorimetric estimation of protein for estimating the actual quantity of protein present in the cerebro spinal fluid. General paralysis was the only condition in which the globulin approached the albumin in quantity in the cerebro-spinal fluid. The Wassermann body was probably formed in the meninges, but this could not be considered proved. The persistence of a positive Wassermann reaction in the cerebro spinal fluid was the strongest proof that the patient was suffering from general paralysis, not cerebro-spinal syphilis.

Colonel L. W. HARRISON (London) called attention to the fact that the term "spirochaemia" had now been discredited by its sponsor, Mr. Clifford Dobell. A compromise might possibly be found by testing the cerebro-spinal fluid for the first time in cases selected according to their behavior to the first course of treatment. He had found at St. Thomas's Hospital that cases which were still sera positive at the end of their first course of treatment remained so for numerous subsequent courses, in many of these the cerebro spinal fluid was persistently positive. On the other hand, he had not found a single positive cerebro spinal fluid in a case with a negative blood reaction at the end of the first course of treatment. He thought, therefore, that only those patients with a positive blood reaction at the end of the first or second course of treatment need have the cerebro-spinal fluid investigated, though it should be examined in all cases before discharge from treatment. Some means ought to be found for making the titration of the non-responsive cases react better. Very little work had been done on the subject, but Major Pettit had repaid some time ago that at Rochester Row were positive early cases had been made responsive by the administration of thyroid extract. If this means or by protein shock therapy something might be done to change the outlook. He was convinced that the employment of arsenobenzol simultaneously with another metal was followed by a much smaller incidence of neuro palsies than when arsenobenzol was given alone or was followed subsequently by a course of mercuric bismuth. In his own clinic, where the combined method was used, there had not been a single case of a cerebellar palsy, while at Johns Hopkins, where the "standard" principle was followed they had had 53 cases of retro-recurrence out of 2,500 cases of early syphilis. In the early days of arsenobenzol therapy, when salvarsan was used alone, there had been a large number of neuro-recurrences and in his own experience it had been mostly in the purely arsenobenzol-treated cases that clinically manifest recurrences had occurred. If a system such as the simultaneous arsenobenzol and mercury (or bismuth) treatment was attended by a smaller incidence of neurosyphilis than was the case when arsenobenzol was employed first and mercury (or bismuth) afterwards, the former seemed preferable.

Mr. VOOR (Edinburgh) read a preliminary note of a test devised by Dr. W. O. KERNACK and MRS. L. WRIGHT and KERNACK had shown that when casein gum benzoin was precipitated by varying concentrations of cerebro spinal

fluids of different degrees of acidity, the abnormal fluids from a case of general paralysis of the insane were characterized by the development of a zone at a pH 5-8, under conditions which precluded the appearance of this zone when a normal fluid was employed. Syphilitic serums were in general distinguished from normal serums by the development of a similar zone at a concentration of serum varying from 1/4 to 1/16 of the undiluted serum. It had previously been suggested that this abnormal zone of precipitation might be occasioned by the presence of a protein of high iso-electric point. It had been found that elupaine, a protamine derived from herring milts, when added in the requisite small amounts to normal cerebro-spinal fluid or serum, caused these fluids to simulate syphilitic fluid and serum in their behaviour towards gum benzoin. An attempt had been made to obtain evidence as to whether a basic protein was actually present in excess in syphilitic body fluids. The reaction of Sakiguchi (development of a red colour by protamines and other compounds containing a free guanidine group when treated with naphthol and sodium hypochlorite) had been slightly modified and applied to syphilitic serums and cerebro-spinal fluids. The preliminary results indicated that in fluids and serums of syphilitic origin the red colour developed more readily than in normal ones, and a high degree of correlation appeared to exist between the results of this colour test and the Wassermann test.

Dr. FREDERICK SMITH (Boston, U.S.A.) agreed that it was of great importance to make the taking of cerebro-spinal fluid from patients by lumbar puncture as painless and free from unpleasant after-effects as possible. He said that by using a local anaesthetic and a small needle, and keeping the patient in bed, he was able to make this operation quite free from drawback.

The PRESIDENT of the Section gave a clinical demonstration of about twelve cases of neurosyphilis, especially with a view to showing the results of treatment, chiefly by triprotinamide, which he had used in large doses without ill effect but with great benefit to the patient. The cases included several of juvenile general paralysis, also of acquired general paralysis of the insane, and of tabes. In many of these cases the results of treatment were striking and impressive. The President did not claim that it was possible to restore the afflicted individual to a strictly normal condition, but he did suggest that they were often able to arrest the degeneration of the nervous system and return the patient as a useful member of society, able to work and self-supporting.

## DISCUSSION

OR

### EPIDEMIC ENCEPHALITIS.\*

#### I—EPIDEMIOLOGICAL CONSIDERATIONS

BY

IVY MCKENZIE, M.D., F.R.F.P.S. GLAS.,

Visiting Physician, Victoria Infirmary and Eastern District Hospital, Glasgow

HAD it is not expected that in opening a discussion the speaker should make a systematic survey of the subject under review. He may assume that those who may take part are already familiar with the main facts and features of the subject, and it is his business to make appropriate and, if possible, provoking remarks, thus focusing attention on some of the problems suggested by his own experience.

In seven successive years, from 1918 till 1924, the attention of the profession in Glasgow was directed to a "new disease," accounts of which had come during the same period from various parts of the world, and a description of which had already been given a year earlier by von Economo in Austria. That it was new admits now of no question, for there is nothing in the literature of

medicine to compare with the phantasmagoria of disorder manifested in the course of this strange malady. There is scarcely a sign or symptom of nervous derangement which did not at one time or another make its appearance during the epidemics. Into the maze of contradictory phenomena it seemed almost impossible to read anything like a rationalized order of events which might be termed a disease entity. Profound and prolonged torpor, protracted and resistive sleeplessness, paralysis, violent jerking, chorea, athetosis, and convulsions, pruritus referable to the head, limbs, and internal organs, every conceivable anomaly of movement of the external and intrinsic muscles of the eye, giddiness and rotatory displacement of the body, abnormal reactions of alimentary tract, emaciation, and respiration, delirium, muscular excitement and fever, comprise some of the outstanding features of this picture of chaos.

The original attempts to interpret the phenomena in the light of nosological principles took various directions. An anatomical basis was soon established in the non-purulent form of encephalitis which was discovered in every case which came to *post-mortem* examination. One result of this discovery, however, was to transfer the confusion to another field of discussion. Non-purulent encephalitis had been described in a variety of diseases. It was present in the cerebral form of poliomyelitis, in the cerebral paralysis of children, in We尼克's syndrome, and as a sequel of a number of acute infections, chief among these being influenza.

The prevalence of influenza at the time of the outbreak lent colour to the view that the new disease was associated with that infection. There were others who, inspired either by vision to "new diseases" or by doubt as to the existence of anything which might be termed a "disease entity," sought refuge in the proposal to regard the phenomena as a form of post-encephalitis. Objection, moreover, was taken to the term "lethargic encephalitis," because, on the one hand, lethargy is not invariably present, and, on the other hand, the morbid reaction was not always confined to the encephalon.

Classification of symptoms, pathological anatomy, and logical disputation ruled individually and collectively to unravel the tangle which the initial stages of the epidemic presented. The efforts of the laboratory were no more successful, for examination of the cerebro-spinal fluid and bacteriological investigation afforded no data of importance, and experimental research gave no results. It is a striking commentary on the nature of morbid processes, and on the part which the clinician plays in their interpretation, that the disease had to reveal its own identity in the course of time before it could be even partially understood. It soon became apparent that, however obscure the microbial origin, however bizarre and baffling the preliminary disturbances, the tendency of the human organism to preserve its identity found expression in the long run in sequelae which constituted a fairly reliable standard of reference. It is just this issue of encephalitis in peculiar and characteristic sequelae which justifies its recognition, not only as a disease entity, but as a new disease.

For what is it that constitutes a "disease entity" or a "new disease"? The physician is concerned not, like the naturalist, with a wide range of different organisms theoretically adapted in an average way to an average environment, but with a single organism, the human subject, striving to preserve its identity in adverse circumstances. In this struggle all those tendencies and activities which are stabilized in the processes of normal life assert themselves. The conflict is not confined to the part first afflicted. The unity of the organism provides for the participation of a variety of immediate and distant reactions in the attempt to maintain or restore order. If the initial assault be severe, as in an acute infection or a cerebral haemorrhage, confusion and disorder are likely to prevail. If this stage be survived, the course of events will be determined by the extent of the damage and by the efforts of the organism, successful or otherwise, to restore a state of equilibrium.

It is the organic substratum to the chaos of disease that has a deciding influence on the course of the morbid process. It determines the tendency of disease to manifest

\* This discussion took place in the combined Sections of Mental Diseases and Neurology at the Annual Meeting of the British Medical Association, Edinburgh 1927, under the chairmanship of Professor Edwin B. A. S. S. S.

itself only in a limited number of ways and it also determines the more or less constant features of each manifestation. These tendencies are exhibited to advantage in disorders of the great integrating systems of the organism, and especially in the nervous system it is just these tendencies that render possible the classification of disease.

There enter into the concept of a disease other considerations which have reference to its incidence, as well as to its course. In the case under review we attribute its origin to an infective agent; we interpret the initial symptoms as due to the irritation and destruction of nervous elements for which the poisons of the infective agent have a special affinity; we explain the late and permanent symptoms as expressions of partially successful or unsuccessful efforts of rehabilitation.

In claiming for lethargic encephalitis the status of a new disease entity it is contended:

- 1 That while nothing is known of the toxic agent except that it produces encephalitis, it is not the toxic agent of influenza or of poliomyelitis or of herpes.
- 2 That the sites of toxic reaction in the central nervous system are peculiar to lethargic encephalitis and are distinct from the sites involved in other forms of encephalitis, such as cerebral influenza, poliomyelitis, Wernicke's disease and the cerebral palsies of children.
- 3 That the sequelae of encephalitis while they are the hall mark of the disease are not phases of progressive infection but phases of attempted adaptation.
- 4 That the history of the successive epidemics in Glasgow indicates a change of type which is not recognized in any other infection of the central nervous system.

These contentions are based on an experience of the disease extending over nine years. During this period about six hundred cases have been examined, and two hundred of these have passed through my own wards in the Forth District Hospital and Victoria Infirmary. The brain and spinal cord of forty cases which came to the post-mortem rooms have been examined. Through the courtesy of Dr. Chalmers and of Dr. MacGregor I have been in constant touch with the Health Department where a very thorough and extensive investigation of the problem has been carried on from 1918 till the present time. I have also had the advantage of regular collaboration with my colleague Dr. Marshall.

### 1. The Toxic Agent

I cannot pretend to be conversant with the literature on this aspect of the problem, but there does not seem to be any reason to believe that the site of infection or the character of the organism have been recognized.

### 2. Pathological Anatomy

The feature of the post-mortem evidence was the absence of change visible to the naked eye. This was all the more striking in view of the pronounced character of the clinical disturbance. Apart from general congestion, nothing abnormal was noted beyond isolated greyish specks in the basal nuclei and mid brain of six patients who died in the acute stage and a relative poverty in pigment in some of the cases which came to necropsy after prolonged Parkinsonian illness. In the spinal cord of five cases minute areas of infiltration in the posterior cornua could be seen on naked eye examination.

This is in marked contrast with what we have observed in other cases of non-purulent encephalitis. In four cases of influenza areas of infiltration, some of them as large as a shilling, were visible on the cerebral cortex. (One of these showing naked-eye changes in each island of Reil is exhibited in the Pathological Museum.) In two cases of encephalitis due to the toxæmia of pregnancy extensive hæmorrhagic exudates could be seen with the naked eye in the basal nuclei and mid brain. (One of these is exhibited in the Pathological Museum.) In a case of Wernicke's disease extensive hæmorrhagic softening was seen in the mid brain, and in lesser degree in the basal nuclei and cerebral cortex. Two cases of poliomyelitis were observed in which translucent reddish areas of

softening were visible in the cerebrum and mid brain as well as in the anterior cornua of the cord. There are on record cases of non-purulent encephalitis in which there were no naked-eye signs of disease in the brain on post-mortem examination but the case is generally admitted to be true. It is thus permissible to draw the general conclusion that the encephalitis known as lethargic encephalitis differs from other forms of encephalitis in that there is on the whole an absence of naked-eye signs of disease in the central nervous system. No account need here be taken of the encephalitis due to syphilis, tubercle, malaria or trypanosome infection for these obviously belong to a quite different category.

With regard to microscopic lesions a distinction can be drawn between the cases which died in the early stage of the disease and those which came to post-mortem examination after a prolonged Parkinsonian illness. In the former the lesions are diffuse and of a moderately acute inflammatory character, and as pointed out by Turnbull and McIntosh and Douglas McAlpine and others tend to be more pronounced in the basal nuclei of the cerebrum and in the mid brain and especially in the mid brain and in the substantia nigra of that region. Occasional foci of reaction may be noted in the cerebral cortex, pons, upper reaches of the medulla, and in the posterior cornua of the cord. The anterior cornua nuclei are not involved. The inflammatory reaction is represented in perivascular infiltration, occasional hæmorrhage, deposits of salts in the vessel walls and surrounding tissues, degeneration of neurones and occasional neuronophagia and proliferation of glial cells. The reaction is not so intense as in poliomyelitis and in influenza, and is quite different from that in Wernicke's disease or in the encephalitis of pregnancy which is essentially hæmorrhagic and not of the nature of a true inflammation.

In the Parkinsonian syndrome there is a consensus of opinion that the most pronounced lesions are in the substantia nigra. Our own findings in this respect accord fully with those of Jacob Douglas McAlpine and others who have gone carefully into the problem. It is questionable, however, whether the depigmentation, degeneration of neurones, demyelination, gliosis and slight vascular change in this region are accurately interpreted as inflammation, or, in other words, is a process in which the infective agent is still active. I am not convinced that the histological appearances resemble those observed in such chronic affections of the central nervous system as syphilis, tubercle, malaria or trypanosomiasis. On the other hand, I am in agreement with Hoffmann that in some cases there are changes though of a minor degree in the basal nuclei of the cerebrum. The possibility must be taken into account that the degeneration of the substantia nigra is not an isolated lesion accountable for the clinical phenomena in the sense in which anterior cornual degeneration accounts for the disabilities of poliomyelitis or destruction of the motor cortex accounts for hemiplegia of the upper neurone variety. It is more likely that the Parkinsonian sequelae are the expression of a disordered function of the whole compendium of reflexes related to the basal nuclei of the cerebrum, the mid brain and the vestibular apparatus, and concerned with the regulation of those phases of automatic posture which render voluntary movement possible. Histological evidence in those cases which died in the acute stages of the disease indicates the implication of the whole series of nodal centres of correlation between the caudate nuclei and the vestibular nuclei. Such widespread involvement is presumably the basis of an original derangement or function of this extensively consolidated mechanism, and the exhaustion and degeneration of the substantia nigra may quite well be a by-product as well as a contributing factor to the subversive process. Very little is known of the functional anatomy of the substantia nigra. Douglas McAlpine makes a very significant remark as to the difficulty of determining the condition of the nerve fibres which course to and from it. A solution of this problem would certainly throw much light not only on the Parkinsonian syndrome but on the physiology of the basal nuclei and of automatic movement.

The results of pathological investigation warrant a general

statement on the nature of the disease. The toxins of encephalitis show a predilection for the great correlating centres of the nervous system—that is, for the grey matter on the afferent side of the proprioceptive system, for certain nuclei in the base of the brain, and for the posterior cornua of the cord. It is significant that there is practically no evidence of disease in the occipital cortex, in the red nuclei, or in the anterior cornua of the cord. In sharp contrast with this is the affinity of the toxins of influenza for the cortex and of the toxins of poliomyelitis for the anterior cornua.

### 3 The Sequelae of Lethargic Encephalitis

The initial signs are varied. Sudden or insidious in its onset it may be mistaken for acute meningitis, haemorrhage, influenza, acute abdominal disease, lumbago, disseminated sclerosis, chorea, epilepsy, and other conditions. The prevalence of an epidemic was often the most reliable clue to a diagnosis. Frequently it was only when the acute stage had passed and the characteristic sequelae appeared that it was possible to recognize the real nature of the disease. But these sequelae are characteristic and peculiarly distinct in the manner in which they appear in children, on the one hand, and in adults on the other.

In the case of children the main disorder consists of profound emotional instability with perversion of conduct. Eruptions of excitement with uncontrollable impulse, often expressed in outrageous and criminal conduct, afford the evidence of a serious dissolution of nervous integration in the early stages of the disease. There is no clouding of perception as in epilepsy, for when the spasm has subsided there is clear recognition of what has happened, and often in expression, even a precocious expression, of regret. The presumption is that the peculiar character of the sequelae in children is determined by the fact that the disease has supervened during the early developmental period, and that normal dissolution has occurred in the basal structures before the association centres of the cerebrum have become consolidated with each other and with the lower automatic centres over which they are destined to exercise control. When, at a later stage in children, a Parkinsonian phase develops, the psychomotor excitement abates. I know of only one case out of fifty in which recovery may have occurred.

The Parkinsonian syndrome, the common sequel in adults, may emerge immediately from the acute stage or may not supervene for months or years. It comprises in its general uniformity of expression a great variety of somatic and visceral disorders, including inhibition of movement, tremor, excessive salivation, greasiness of the skin, outbursts of sweating, abnormality in sugar metabolism, attacks of hypotension, and occasionally excessive increase in weight. Combined in varying degree in the single characteristic sequelae are the features of two distinct diseases—of pulvis agitans and of katatonie. It is a pulvis agitans with vegetative disorder, and it is a katatonie without the stupor. It is inconceivable that such a varied disorder should be due to a lesion confined to the substantia nigra in the sense in which infantile paralysis is due to destruction of the anterior cornua, or hemiplegia to ablation of the motor cortex.

I have pointed out elsewhere that the initial involvement of the oculi and vestibular apparatus is consistent with the presence of acute changes in the basal nuclei and brain stem. The puits of the cortical nervous system originally affected are essentially those whose integration is concerned in the postural and automatic movement necessary for voluntary control by cortical activity. This great compendium of reflexes has its nodes of integration in the basal nuclei of the cerebrum, in the mid-brain, in the vestibular nuclei and in the posterior cornua of the cord. It is known to physiologists as the proprioceptive system and it is suggested that the Parkinsonian sequelae is due to a functional derangement of this system incident to destruction of some of its vital parts in the early stages of encephalitis. This conception is consistent with the anatomical findings on which a comparison was made with poliomyelitis and influenzal encephalitis. The lesion in

poliomyelitis is in the anterior cornua, in influenza in the occipital cortex and in lethargic encephalitis in the correlating centres in the basal nuclei and posterior cornua.

The manner in which a great neuro-muscular compendium may be functionally deranged is seen to advantage in the case of the respiratory mechanism, in which normal health may be impeded by the pathological reactions of coughing, sneezing, hiccup or the closely allied phenomenon of vomiting. Pathological physiology has to do, not merely with absence, diminution, or increase of normal function, it deals with the aberrant irradiation of stimuli and with subversive reactions which are absolutely inconsistent with normal function, but which may be kept within limits by stabilized organic tendencies. The pathological physiology of the Parkinsonian syndrome is the study of an organized chaos, a chaos induced in the first instance by destruction of important integrations and reorganized on an unstable basis in the process of rehabilitation. A suggestive analogy may be found in cardiac disease, in which the circulatory failure, which is often long delayed, bears some resemblance to the Parkinsonian syndrome. The adaptive process is not confined to the heart itself. It extends to the peripheral circulation in which altered tonus plays a part. When the subversive element in the adaptation gains the ascendancy the failure due to oedema and waterlogging occurs in the peripheral circulation. It is not unlikely that the progressive disability in the Parkinsonian syndrome is due, not to the continued activity of the original toxin, but to aberrant irradiation and subversive tendencies in a poorly adapted proprioceptive system. This conception is supported by the remedial effect in some cases of intensive treatment with belladonna and hyoscine.

The outlook in this sequelae is no more favourable than that in the special disorder in children, although great improvement may occur and progress may be staved in many cases by the treatment mentioned.

Of those who survive the acute stage few make a recovery. Not more than sixty, out of three hundred, were free from all signs and symptoms two years after the infection. It is a remarkable fact that in a disease involving vital centres of the brain and producing such pronounced aberrations of conduct and impediments to behaviour, there should be practically nothing in the nature of dementia in the sense in which that term is understood by the alienist.

### 4 History of the Disease in Glasgow

Looking back on the history of the disease in Glasgow several points of interest arise. Profound lethargy marked the earliest cases in 1918. The first six cases I saw never came out of the state. In 1919 the initial symptoms were often those of acute excitement. In 1920 (as, to a lesser degree, in 1924) a large proportion of those affected were children, and the majority of these showed choreiform agitation. In 1921 and 1922 the majority affected were adolescents and adults, and the initial symptoms were again severe, although in some cases they were insidious and took the form of transient giddiness or diplopia. In a few cases the disease began with epileptic seizures. In 1923 and 1924 the onset was, as a rule, more gradual, and we now know from the sequelae which have developed in the interval that the infection may occur without producing any incommence that could reasonably be ascribed at the time to encephalitis. In 1924 some cases were so misleading as to determine a definite diagnosis of disseminated sclerosis. In one instance Dr Marshall and I demonstrated on several occasions, as a typical example of disseminated sclerosis (ankle clonus, positive Babinski, absence of abdominal reflexes, nystagmus), a case which afterwards became lethargic, and which, on *post-mortem* examination revealed the definite evidence of encephalitis in the basal nuclei and in the posterior cornua. There was no histological evidence of disseminated sclerosis. I have from *post-mortem* records of similar cases. It is important to note that the optic nerves were normal in each case. There has been no epidemic since 1924, and in the interval I have not seen a single acute case in which the diagnosis of lethargic encephalitis was unequivocal.

## II—THE PATHOLOGY OF EPIDEMIC ENCEPHALITIS

BY

J. CODWIN GREENFIELD, M.D., F.R.C.P.

### 1. Etiology of the Virus of the Disease

EPIDEMIC encephalitis resembles many of the common infectious diseases in being caused by a virus which no one has seen, or has been able to grow in an artificial medium. Whether it has been possible even to transmit the disease to animals is still a matter of dispute. Although the most recent work tends to confirm rather than to discredit the assertions of those who claim to have done so. This work is of the very greatest interest and it is of special importance in that it seems to clarify some of the difficult etiological problems which the disease presents. In particular, it seems to shed light on the question why the more remote forms of the disease are less often followed by progress or sequelae than those in which it begins more insidiously.

Those who have claimed to infect animals with the disease must be divided into two groups. The protagonists of the first group are Loewy and Strauss of New York, and Kling and his associates in Sweden. Certain of those who obtained the earliest positive results in this country must also be included in this group. These workers used either brain pulp or cerebro-spinal fluid blood nasopharyngeal secretion urine or feces from cases of encephalitis for injections into rabbits. The animals showed no symptoms, but when they were killed and their brains examined microscopically about 50 per cent were found to show lesions very similar to those of the human disease. In particular, foci of lymphocytic exudate and perivascular infiltration. This disease could be transmitted from rabbit to rabbit indefinitely but again only about half of the rabbits became infected. The claims of these workers were shown to be invalid by McCartney who examined 372 stock rabbits at the Rockefeller Institute and found similar lesions in the brains of 55 per cent. Following on the work of Bull and Oliver he was able to trace the etiology of the encephalitis in the animals to a protozoon which Loewy has named the *Eucyballozoon cucullatus*. This comparatively harmless parasite had obviously caused an epizootic among the experimental animals which happened to resemble encephalitis lethargica in its histological characters. These results must therefore be completely discounted.

The other group of workers who have transmitted encephalitis to animals claim that the etiological agent is identical with that of herpes febrilis differing from it only in possessing a greater affinity for the nervous system. The first to transmit this virus from the human disease were Levaditi and Harrier who in 1920 produced the symptoms of acute encephalitis in a rabbit by the subdural injection of brain tissue obtained from a case of encephalitis lethargica. It is noteworthy that the patient from whom this material was taken had facial herpes at the time of death. Following on this Doerr, Schürbel and Berger in Bielefeld, Luger and Landner in Vienna and Perdrin in London have produced encephalitis in rabbits by the inoculation of either brain pulp or cerebro-spinal fluid. All these workers state that it is extremely difficult to infect animals and that only a very few of the human cases of encephalitis examined yield a virus which is pathogenic for animals. But when encephalitis is produced in the rabbit it can usually be transmitted as a rapidly fatal disease from animal to animal.

It has been known since the pioneer work of Gruter and its confirmation by Krüppel and Löwenstein that fluid obtained from the vesicles of dendritic ulcer or of libral herpes contains a virus which when inoculated on to the scarified cornea of rabbits produces a keratitis accompanied by copious purulent conjunctivitis and often followed by rapidly fatal encephalitis. Levaditi and Harrier in ignorance of this work, inoculated the virus which they had obtained first into the anterior chamber of the eye and later on to the scarified cornea of rabbits and in both instances produced not only local lesions but in encephalitis from which the animals died in ten to fourteen days

after inoculation. It only remained for Blane, working in the Pasteur Institute at Athens, to compare the virus obtained from these two different sources, and to prove by crossed immunity experiments that they were identical. It is true that certain differences are noticeable, not only between encephalitis and herpetic virus but also between different strains of encephalitic virus. Some of the latter constantly cause both keratitis and encephalitis, others produce a less severe keratitis but when injected into the brain produce a fulminating encephalitis. On the whole, the herpetic virus is more virulent for the cornea, and less virulent for the brain whereas the encephalitic virus may be comparatively avirulent for the cornea. But when keratitis has been produced by a virus of either kind, it is impossible to reinfect that cornea with virus of any other strain although it still remains sensitive to inoculation by other viruses, such as that of vaccinia.

The only serious criticism brought against the theory of the identity of the virus of herpes febrilis with that of encephalitis lethargica is that in the few instances in which encephalitis has been caused in rabbits by the inoculation of human material the virus of herpes febrilis had been accidentally included. This may well have been so in Levaditi's first case in which herpetic vesicles were present at death. In fact Flexner obtained an apparently identical virus from the cerebro-spinal fluid of a convalescent case of neuro-ophthalmitis. Herpes is a very common and widespread disease among mankind and the fluid from herpetic vesicles is constantly pathogenic to rabbits. Not only so but saliva and nasopharyngeal washings of those who are susceptible to herpes are frequently sources of herpetic virus. It would, therefore, not be surprising if occasionally virus of this kind reached the cerebro-spinal fluid during life or the brain after death. This opinion is strengthened by the observations of Teissier, Marinresco, and others that patients suffering from encephalitis lethargica are not more but less immune to herpes inoculated cutaneously than are the generalities of mankind. Levaditi himself thought to cure encephalitis lethargica by injecting the virus of herpes into the lumbar canal of patients and produced in many of them facial or labial herpes. There is therefore no such crossed immunity in the human subject as exists in rabbits. But it is notorious that human immunity to herpes febrilis is very slight. Even in the rabbit immunity to herpes does not last long and shows many peculiarities. It is definitely a tissue immunity and not a humoral immunity. Mixing the serum of an immune rabbit with virus does not reduce its virulence although the addition of immune brain pulp sometimes does so.

Peidrau found that the brain pulp of rabbits immunized by cutaneous inoculation contained aggressive virus in addition to immune bodies and that when kept in glycerin from two to three weeks the aggressiveness remained active whereas the immune bodies deteriorated. Acting on these observations he fortified the virus contained in human brain emulsion by adding to it before inoculation twice as much brain pulp from a recently immunized rabbit. In this way he produced encephalitis in rabbits with material which, when injected alone proved ineffective. He also made use of the negative phase of immunity by performing his intracerebral injection the day after a dermal inoculation, or even by giving on four successive days two dermal and two intracerebral inoculations. In this way he was able to produce encephalitis in rabbits with material from each of three fatal cases of encephalitis lethargica. His work is of the utmost importance since it seems to indicate why so many of the earlier experiments had failed. He showed in the first place that the most virulent human virus which if preserved in glycerin long enough would rid it of the accompanying immune bodies produced in rabbits a fulminating encephalitis fatal in four days from the time of inoculation, but if injected fresh and without the help of aggressives, produce no symptoms at all. And secondly that the most virulent material especially that obtained from less acute cases of the disease might produce in rabbits a subacute form of encephalitis with lethargic symptoms. These symptoms were quite unlike those of the ordinary herpetic encephalitis, but were exactly

similar to those seen if herpes virus were inoculated intracerebrally into immunized animals at a time when their immunity was passing off. In both cases the brains of these animals did not yield any virus which could be transmitted to other animals. From these observations he concluded that in the human disease one of three things may happen:

(1) The development of a local cellular immunity which overcomes the infective agent and leads to a complete recovery. (2) The development of a state of cellular immunity which only partially overcomes the infection, the final issue being either a fatal one or a chronic infection. (3) Failure of the development of any immunity and a quickly fatal result.

Cases of type (3) would yield a virus which, being free from immune bodies, would be easily transmissible to rabbits, but the majority of cases were of type (2), and material from them would be either completely non-infective or might produce a subacute encephalitis from which no further active virus could be obtained. If, however, it were freed from immune bodies by prolonged glycerination, or if its virulence were increased by the addition of "aggressins," such material might produce a typical herpetic encephalitis transmissible to other rabbits. Now the experimental work with herpes has shown that the immunity obtained by the inoculation of a weak virus is less complete and more evanescent than that given by a strong virus. It seems, therefore, likely that in the human subject an infection by a comparatively non-virulent strain might fail to produce sufficient cellular immunity to kill off the virus completely, and that it might spread in the brain, attacking only those cells which have less power of resistance. It may be, as Peidrau has suggested, that certain cell groups are less resistant than others, and possibly the melanin-bearing cells of the substantia nigra and substantia ferruginea are particularly susceptible. If so, it is easily understood why cases in which the initial cerebral symptoms are of the slightest character frequently go on progressively to a state of post-encephalitic Parkinsonism.

## 2 Clinical Pathology the Cerebro-spinal Fluid

The only laboratory examination which gives any assistance in arriving at the clinical diagnosis is that of the cerebro-spinal fluid. Here the evidence is sometimes negative rather than positive, as, even in the early stages, the fluid may be quite normal or may contain a slight excess of glucose, which is always of doubtful significance. But usually in the first few weeks of the disease there is a lymphocytosis of 10 to 100 or even more cells per cubic millimetre. In my experience, as well as in that of others, the cells are usually all mononuclear, but occasionally the presence of a varying proportion of polymorphonuclear cells has been reported. In the past I have been inclined to doubt the diagnosis when any considerable proportion of the cells were polymorphonuclear. But in one case in which I found 10 per cent polymorphonuclear cells, the onset of typical sequelae has established the diagnosis, and there appears to be no reason for doubt in Doughty's Sheffield cases, where as high a proportion as 44 per cent was sometimes found. In a case examined histologically by Dr. Iano, as also in one of von Wiesner's, the inflammatory exudate in the brain was largely polymorphonuclear in character and this is the case also in the herpetic encephalitis of rabbits during the more acute stages. In view of these facts I am inclined to alter my earlier opinion and to agree that polymorphonuclear cells may sometimes occur in the cerebro-spinal fluid. It is characteristic of encephalitis that the rise in the cell count is not usually associated with any great increase either in the total protein or the globulin, and sometimes a large cellular excess is associated with a normal protein percentage—the so-called cell-protein dissociation. Excess of protein is exceptional, and a coagulum practically never forms. Yellow or haemorrhagic fluids are sometimes obtained when there has been meningeal haemorrhage, but such cases appear to be rarer now than they used to be. Not uncommonly, the colloidal gold reaction gives curves of the luetic type. Some workers have obtained such reactions in every case examined, others only in 15 to 50 per cent of cases but all are agreed that some change in the colloidal gold is characteristic of the disease. Occasionally fairly strong curves of the parietic type have been

obtained, but these are much rarer. The colloidal gold reaction is of special importance in the post-encephalitic states, as it may give the only evidence of any abnormality in the fluid. The reactions obtained at this stage are usually so weak that the other colloidal reactions may fail to demonstrate them.

## 3 Morbid Histology

The histological picture of the disease is so well known that it would be unnecessary to add anything to it, were it not that there has lately been a tendency to focus attention on the mid-brain, forgetting the cerebral cortex, and to think more of the cellular exudate than of the damage done to the neurons. It has now been definitely established that post-encephalitic Parkinsonism is due to the destruction of the cells of the substantia nigra, and certain evidence, both clinical and pathological, appears to justify the assumption that sometimes the disease lingers on in this region of the brain after it has died out elsewhere. But there can be no doubt that destruction both of these melanin-containing cells and of nerve cells elsewhere in the brain may, and does in fact, take place at a very early stage. I have examined the brain of a case of lethargic encephalitis which terminated on the twenty-third day of the disease in which most of the cells of the substantia nigra had already disappeared.

Now it is easy by any of the ordinary staining methods to establish the disappearance of melanin-bearing cells, as the granules of melanin lie about free in the tissues for some time afterwards. But it is very much more difficult to tell when there has been destruction of some of the cells of the cortex or of the basal ganglia. In the case of the latter organs, cell counts have occasionally been done, and have shown that a certain small proportion of the neurons have disappeared. General shrinkage of the basal ganglia has rarely been taken into account, although it is well known that this may occur and may confuse the cell count. In the cortex comparative cell counts are extremely difficult. But decay of the neurons of the cortex and basal ganglia may be demonstrated in a large number of cases by the collection of lipid granules around the walls of the small vessels in these regions. The majority of these granules appear to consist of the lipochrome of nerve cells, although a certain number may result from the destruction of myelin. Compound granular corpuscles, however, are very rarely seen, and demyelination of the cortical layers is never prominent. There is evidence that lipochrome is not easily metabolized in the tissues, and its appearance in large amounts in the walls of the small cortical vessels after a few weeks of disease may, I think, be taken as showing at least severe damage to, if not destruction of, a large number of cortical neurons.

I have recently examined the brain of a case of encephalitis which ended in coma about four weeks after the onset of diplopia and parasthesia. In all the regions of the cortex examined the accumulation of lipid, not only in the nerve cells but also around the walls of the vessels, was very striking. It was not everywhere of equal intensity, but was usually greatest at the bottom of the sulci, and from here spread outwards in an irregular fashion towards the surface of the brain. Similar collections of lipid pigment were also present in the putamen and crus cerebri, but were less noticeable in the pallidum and optic thalamus. Unfortunately I did not have an opportunity of examining the mid-brain in this case. In a post-encephalitic case in which, in addition to Parkinsonian bradykinesia, there was pronounced lethargy, similar perivascular collections were found in the cortex, especially in the occipital poles. In the frontal cortex there was, in addition, a definite disappearance of nerve cells.

We are therefore justified in considering encephalitis lethargica as a disease in which there may be widespread and severe destruction of nerve cells, not only in the brain stem, but also in the cortex, and it seems clear that this neuronal degeneration is quite independent of any inflammatory cellular reaction that may be present. It is of interest to note that such skilled observers as Bonnamy and Bok and Flexner and Amoss have demonstrated a similar direct action by the virus on the nerve cells in the herpetic encephalitis of rabbits. This conception of

the pathogenesis of the disease is supported by the observations of McNulty, Borden and others that in the most rapidly fatal cases there may be little or no inflammatory exudate or perivascular cuffing. It is not a new conception but it is perhaps a useful one to keep in mind when we try to visualize the pathological substratum of the mental sequelae of lethargic encephalitis.

### III—CHRONIC ENCEPHALITIS

GEORGE RIDDOCH, M.D. ABERD. I.I.C.P.LOND.  
Assistant Physician, London Hospital and General Hospital,  
Queen's Square.

Clinical and pathological experience has shown that encephalitis lethargica like neuro-synclitis and disseminated sclerosis is essentially a chronic disease. For whatever it declares itself acutely or insidiously and however complete the recovery from the initial phase may appear to be, in a large proportion of cases the infection which has evidently lain dormant for weeks, months or years again becomes active and gives rise to the grave disabilities with which we are familiar. The distressing result is that we never know when the patient is cured. At present we are at a prognostic impasse.

The disease commonly begins as an acute illness with the symptoms and signs of which we are not here concerned. Suffice it to say that it may be even with high fever and general constitutional disturbance or subacute with or without distinctive features, such as lethargy and diplopia, or so slight that it is looked upon as a trivial event. The mortality rate has been differently estimated, but it probably lies between 20 and 30 per cent. Of the survivors some are left with residual troubles that may in time disappear or become stationary or progressive. Others remain well for so long that we hope that the cure is complete. But there is always the danger of relapse and the development of late manifestation.

An important group of cases is that in which the disease seems to be chronic from the beginning. Of course there is the possibility that the initial attack has been missed or passed over as either influenza or a common cold. But with that in mind cases are not infrequently met with in which the most searching inquiries fail to reveal the history of a suspicious illness.

#### Clinical Forms of the Disease

Although the virus of encephalitis lethargica has a predilection for the brain stem and corpus striatum no part of the nervous system is immune. It has to be remembered also that the disease is a general infection with special affinity for the neuraxis but with powers to attack other structures as well, notably the ducts and glands. The variability of its clinical manifestations is therefore not surprising. At the same time there is the danger of an dealing with a new disease about which our knowledge is far from complete or oversteering it by anthropomorphism and of using it as a harbour for our diagnostic difficulties. The clinician with his mind attuned to new possibilities requires the constant check of pathological investigation. Nevertheless chronic encephalitis is already surrounded by the occurrence of many distinctive syndromes of function and others doubtless will yet come to light.

It is useful to separate various clinical pictures or syndromes from the diverse manifestations of the disease. With widespread infection of the central nervous system and involvement of physiological functions it is practicable. More convenient if less scientific is the classification in correlation grouping of symptoms and signs into one or more clinical pictures. The minimum anatomical involvement of the brain although different physiological units may be involved. But here again the liability to recurrence may alter the clinical picture throughout the course of the complaint. The classification on this basis becomes complicated and inadequate.

If the time at my disposal I will not attempt more than a brief outline of some of the physical disorders of func-

tion presented by the disease in its late stages. The mental changes, which are so important, especially in children, are dealt with by Dr Marshall.

#### The Parkinsonian Syndrome

This is the most common disability of a general kind in adult resulting from encephalitis lethargica. It occurred, for example in 70 out of 129 cases studied by Mac Leven. It may appear rapidly during the acute illness when there is some hope of improvement. But more often its evolution is slow and progressive from the outset, although in its course there may be stationary periods.

The clinical picture of the disorder in its fully developed form is now so familiar that to describe it afresh would be unnecessary. It would be more profitable to consider some of the features which indicate the mild Parkinsonian state. These are often slight but as a rule so alter the patient's appearance and behaviour that they at once arrest attention. He too is now aware that something is wrong and his constant complaint is of a sense of weariness and reduction in vigour. The symptoms will be discussed later in more detail since they may be present in extreme form without gross physical signs. With them, but not invariably, there is lethargy or insomnia which may last continuously for many months or disappear for a time and recur. The sleeplessness is particularly resistant to treatment. Such disorders of sleep are of course, not peculiar to the Parkinsonian state but may form part of any of the clinical pictures of chronic encephalitis lethargica.

The early signs of Parkinsonism are found more in the upper part of the body, especially the face, than elsewhere. The face is greyish, the expression tends to be fixed, the eyes staring, the mouth often a little open, and a pool of saliva may be seen between the lower lip and the teeth. The palpebral fissures may be wide or narrow but blinking is infrequent and quivering of the lids when an attempt is made to open or shut the eye is a constant sign. Diplopia, squint and nystagmus are less commonly found than in the acute stage of the disease but defects in ocular movement or pupillary reaction are never absent. The external ocular muscles are supranuclear in origin and consist of defective conjugate movement especially in convergence. A striking abnormality that is sometimes observed is intermittent spasm of the elevators of the eyes. The pupils are not usually altered in size or shape but are often unequal and almost always show some disturbance of reflex action to light or of accommodation or both. They may be fixed. Impairment of the pupillary accommodation reflex and of conjugate convergence of the eyes go together. Although there may be no definite diplopia, mistiness of vision from defective muscle balance or ocular paralysis is often complained of and may be a persistent defect.

A characteristic feature of the Parkinsonian state is the relative immobility of the affected parts even in the apparent absence of rigidity. It all events to the ordinary clinical tests. In its minimal development this is evident in slight fixity of the facial expression and of the eyes, a tendency to hold the head till a reduction or the associated swinging movement of the arm in walking and a diminution in the natural fluidity of the healthy individual.

Along with the face one upper limb is usually slightly affected. In the mild cases of Parkinsonism and when there is any rigidity its cog-wheel character can best be detected at the wrist. Or the other slight signs of the Parkinsonian syndrome two only will be mentioned—namely, excess of saliva in the mouth the result of diminished activity of the swallowing reflex and micrographia. Excess of saliva involvement of the right hand may also be portrayed in the handwriting which becomes smaller the reduction in size of the letter being progressively evident towards the end of each line and even more so the script goes on. In addition the line forming the letters are slightly wavy although tremor of the hand may not be seen.

#### Involuntary Movements

Involuntary movements of many different kinds are amongst the common manifestations of chronic encephalitis

**Lethargy.** The time of their appearance in relation to the onset of the disease, their duration, and the constancy of any one form show great variation. More than one variety may be seen in the same patient, and they may change during the course of the illness. Some are slight and almost insignificant, others are large and arresting, and, in a severe case, the body may be in an almost constant state of movement.

Involuntary movements rarely, if ever, occur alone as the sole manifestations of the disease. Mental or physical derangements of some sort are also present, but may be so slight as to be easily missed by the casual observer. Emotional instability and restlessness, especially at night, lapses in behaviour, minor pyramidal or extrapyramidal signs, and oculomotor defects are perhaps the most frequent slighter accompaniments of involuntary movements, but any of the dramatic respiratory disorders may be found.

Mrs. Levy<sup>5</sup> has grouped the involuntary movements of encephalitis lethargica as follows: (1) choreiform movements, (2) bradykinesia, (3) myoclonic movements, and (4) tremors. But, in addition, there are many others—for example, innumerable tics, shuffling and stamping movements of the feet, ocular or glossal spasm, complex automatic actions of the whole body, and the "imitative" movements described by Babinski and Klebs.<sup>1</sup> Brief mention only will be made of some of these abnormal reactions.

**Bradykinesia** is the term used by Marie to denote slow, regular, rhythmic movements, often of great amplitude. Such are torsion of the trunk, sthenoid movements of the limbs, spasmodic torticollis, and grimacing. They are not often encountered.

**Myoclonic movements** are well known in the acute phases of the disease. But they may also appear as late manifestations in any part of the body and persist for months, accompanied by pain and cutaneous tenderness, radicular in distribution. The pain is often severe and persistent, and may continue long after the shock-like muscular contractions have gone. The contractions are rhythmical, at first into which comes but may reach forty a minute, and involve part of a muscle, a whole muscle, or a muscle group. Usually they are of insufficient strength to displace a limb segment. When they are localized, the upper abdominal wall or the diaphragm is most often the part affected, and in the latter case the objective manifestation of the contractions is recurrent hiccup.

Tremor of different parts of the body occurs chiefly as a complication of the Parkinsonian syndrome. Froment and Delor<sup>4</sup> have rightly insisted that, unlike the tremor of paralysis agitans, it occurs as a rule only during voluntary movement or the maintenance of an active posture. In addition to the limbs it is found elsewhere, giving rise, for example, to shivering of the head, clicking of the teeth, to-and-fro movements of the tongue, and a rhythmical sucking action of the lips.

All involuntary movements are aggravated by emotional disturbance and fatigue, and, so far as I know, disappear during sleep.

### Respiratory Disorders

A considerable literature has grown up concerning these striking and diverse abnormalities. At first they were often looked upon as hysterical, a not surprising mistake, for they can to some extent be controlled by voluntary effort, become aggravated by excitement, and are frequently associated with emotional instability and restlessness, especially at night. With some of the more severe respiratory disorders delusions and violence may develop, necessitating the patient's confinement in a mental hospital.

Turner and Critchley<sup>6</sup> have classified respiratory abnormalities into three groups: disorders of rate, disorders of rhythm, and respiratory tics.

Tachypnoea and bradypnoea are usually paroxysmal, the attacks varying in duration from a few minutes to several hours. With increase in the respiratory rate (60 to 100 a minute) breathing is shallow, not necessarily distressing, and there may be no accompanying tachycardia. Sometimes, however, breathing is deep as well as rapid,

and, in prolonged attacks, tetany from overventilation of the lungs may then develop. Tachypnoea is followed by a period of either bradypnoea or apnoea before normal respiration is established. In bradypnoea the respiratory rate may fall as low as 6 per minute and the breathing is deep and often noisy and panting.

The term "dysrhythmia" is used to cover such abnormalities as sighing, apnoeic pauses, breath-holding, and the like. Breath-holding is a most dramatic performance, which may be often repeated, especially towards evening, and occur during sleep (Turner and Critchley<sup>6</sup>). After a few deep breaths the chest is held in full inspiration for as long as half a minute. The head is often thrown back, the limbs may perform various grotesque movements, the face may or may not be cyanosed, and, in the longer attacks, consciousness is sometimes lost for a short time. Noisy expiration follows and normal breathing is then established.

**Respiratory Tics.**—Hiccup, yawning, spasmodic hard cough without expectoration, sniffling, hawking, sneezing, are all included under this heading. They are perhaps most often met with in young patients of school age, who, in addition, show changes in character and are subject to nocturnal excitement.

### Spastic Paralysis and Muscular Atrophies

Evidence of slight pyramidal disturbance is common enough as part of almost any of the syndromes of chronic encephalitis lethargica, especially Parkinsonism, and, since Buzzard and Greenfield described the first case, it has been recognized that hemiplegia, with or without an apoplectic form onset, can occur during an acute attack of the disease. So, also, rapidly developing paraplegia from myelitis has not been unknown in some of the epidemics. But paralysis of either cerebral or spinal origin may also develop insidiously and form the prominent part of the clinical picture. The diagnosis in such cases may be extremely difficult or remain uncertain, but, as a rule, distinctive phenomena are associated with the paralysis, or the history of the illness provides the clue. Thus, Wimmer<sup>7</sup> has described a case of hemiplegia in which the paralysis was gradually replaced by Parkinsonian features. These disorders may occur simultaneously and on different sides of the body, as in one patient I had under observation for several weeks. Another case, where, however, the diagnosis is more doubtful, is that of a man of 53 who, three years after an acute attack of encephalitis lethargica, developed progressive pueria of one lower limb along with nystagmus and unilateral deafness. He was otherwise healthy.

Local muscular atrophies, with or without fibrillation, in different situations have been described by several observers. Thus, Wimmer<sup>7</sup> has recorded an example of wasting of the tongue, and I have it present under my care in a patient with unilateral glossal atrophy with fibrillation. Sicard and Pariz, Froment, and others have described atrophies in the limbs. These are often associated with pyramidal or sensory disorders, clearly pointing to spinal involvement. From histological and clinical evidence it would appear that muscular atrophies may be due to lesions either of the anterior horns or the roots, and, when radicular, there are often in addition severe root pains and cutaneous tenderness which may persist for months.

### Endocrine Disorders

Adiposity, with or without disturbance of the sexual functions, is fairly frequently met with. Duncan<sup>8</sup> found it in 7 out of 83 cases investigated at the London Hospital. One of my patients, a young girl, who became rapidly and grossly fat after an acute attack of the disease, had amenorrhoea lasting for many months. Later she developed exophthalmic goitre, and her weight diminished, but did not fall to normal until she made an apparently complete recovery in eighteen months.

In another case tachycardia, tremor, slight goitre, and emotional instability appeared in a girl a few weeks after she had seemed to recover from the acute phase of her illness, and persisted for many months.

Diabetes insipidus and glycosuria are also occasional late results of the disease.

*Isthmic Syndrome*

Lastly, there is a clinical picture of chronic encephalitis lethargica of which enfeeblement is the constant and main symptom and in which the physical signs may be slight. Insufficient attention has been paid to this not uncommon syndrome.

The condition may follow an acute attack of the disease either immediately or after a variable interval, or develop as a chronic state from the beginning. The patient's complaint is of a more or less persistent sense of fatigue, both mental and physical, not as a rule a mere inertia, but associated with the discomfort of great weariness. There is diminished desire or power for effort, and physical exertion or mental exercise aggravates the sensation of weakness. The patient looks tired and lackadaisical, and his movements and speech are slow and without animation. For a considerable time he may, with difficulty, continue his work, but if the feebleness increases as it usually does, he ultimately gives up the struggle and lies in bed or sits in a chair doing nothing. Unlike the weakness of myasthenia gravis the feebleness is not as a rule much diminished by rest and unlike the neurasthenic the patient does not tend to feel better as the day goes on. He may sleep well or be lethargic, but quite often insomnia is a serious complication.

Especially when there are family responsibilities the results of worry cloud the clinical picture and depression, tearfulness and irritability lead to the common diagnostic error of anxiety neurosis.

This state of fatigue with the sense of general ill health and weariness is common to most, if not all Parkinsonians, but the point I wish to stress is that it quite frequently occurs as the sole or main disability. At the same time, in my experience, some of the patients who are afflicted in this way sooner or later develop the Parkinsonian syndrome but with what frequency I cannot say since the period of observation in many is as yet too short. In one case a man of 40 the characteristic facies and bodily posture began to develop fifteen months after the onset of the illness.

Slight physical signs are almost always found and of these defective pupillary reactions and conjugate movements of the eyes especially on convergence are the most frequent. Sometimes there is a little weakness of voluntary movement of the face, tongue and palate or again mild Parkinsonian signs or involuntary movement such as tremor or facial tic may be seen.

Recognition of this group of cases is important not only from the point of the symptomatology of the disease as a whole but also for the differentiation of these cases from patients suffering from psychogenic disorders with which they are frequently confounded.

In the literature occasional reference has been made to this clinical form of encephalitis lethargica as a "myasthenic" variety of the disease—a term which in my opinion should not be used for between it and myasthenia gravis there are many essential clinical distinctions and complete pathological divergence.

The gaps in this brief outline of the clinical features of chronic encephalitis lethargica will be filled in by subsequent speakers. Our knowledge of the symptomatology of the disease, if yet imperfect is steadily growing but it must be admitted that in regard to prognosis and treatment we are at present profoundly ignorant. With nine years' experience now behind us and a wealth of material at our disposal, much could be done by systematic investigation especially at large hospitals to throw more light on the outcome of the disease and its various manifestations.

## IV—MENTAL ASPECTS OF EPIDEMIC ENCEPHALITIS

BY

POPERT MACNAB MARCHALL, M.D.  
Assistant Physician, Victoria Infirmary, Glasgow

THE disease encephalitis lethargica may be defined as an infection the toxic products of which have an affinity for the grey matter of the central nervous system and so give rise to any of the syndromes of disease of that tissue or to any combination of such syndromes, and which runs a fickle course that may end in recovery, death, or the production of characteristic sequelae.

In seeking to make a helpful contribution to a discussion of this protean disease it seems best not to try to give an epitome of the disease but to choose certain topics suitable for discussion. It is proposed, therefore, in what follows to deal briefly with the following points:

- 1 The clinical importance of the course that the disease runs
- 2 The incidence of the characteristic sequelae of the disease
- 3 The mental state of the restless, naughty child
- 4 The clinical affinities of the Parkinsonian syndrome

## 1 The Clinical Importance of the Course that Encephalitis runs

The chief end of the clinician's work on this disease appears to be to cut out of its protean manifestations various types, and to arrange them in a scheme of classification. Little or no success, however, has attended his efforts in this direction. Of the many schemes of classification of the clinical varieties of epidemic encephalitis that have been drawn up in almost every European tongue no one has met, or is likely to meet, with general acceptance. This general failure to make good in their taxonomic labours has been attributed by the clinicians themselves to the way in which well defined types of nervous disorder succeed each other in the course of the disease. It is not uncommon they have pointed out to see epidemic encephalitis begin as a neuritis and then pass through a series of states akin to chorea, lethargy, and acute mental confusion, each succeeding state blending with its neighbour in a way that eludes the powers of definition. But this failure to define clear cut types of the disease is hardly a matter for regret for while the fickle course that the disease runs may render the work of the taxonomist impossible, it is in itself a most valuable subject of clinical study. In this respect its chief value lies in the fact that a study of the course that the disease runs clinically brings the observer into touch with the morbid process responsible for the production of the clinical types that are the taxonomist's preoccupation. In so far as the clinical varieties that the taxonomist defines are static there is nothing specific about them. There is nothing specific for example about the ophthalmoplegia of epidemic encephalitis even although paralysis of accommodation is commonly met with in that condition. It only regains its specific character when it is reviewed in the light of its clinical history and demonstrated to be an incident in the course of a disease that runs a kaleidoscopic course.

While an epidemic of encephalitis lethargica is raging the diagnosis in the great majority of cases offers no real difficulty. It is another matter however when it is a question of recognizing a sporadic case of the disease. In these circumstances the difficulties of a differential diagnosis is between epidemic encephalitis and the other forms of non-purulent encephalitis may be insurmountable. The same remark applies to the difficulties that arise on meeting an unusual form of chorea, ophthalmoplegia or lethargy. In all these instances however the fact that the condition has occurred in the progress of a malady that has run a fickle course in which divers symptoms of nervous disease have put in an evanescent appearance goes a long way to establish the nature of the disease process at work.

## 2 The Incidence of the Sequelae in Encephalitis Lethargica

It is usual for an interval to elapse between the subsidence of a disease and the appearance of its sequelae. This is far from being the rule, however, in epidemic encephalitis. Not infrequently it happens that a syndrome that has played a more or less prominent part in the acute phase of the disease persists after this phase has apparently subsided. Tics, disorders of the respiratory rhythm, and psychomotor excitement frequently behave in this way. Therefore it is usual for an interval of anything up to four weeks to elapse before the appearance of the Parkinsonian syndrome, it also may follow hard upon, if not actually merge out of, the acute phase of the disease. On the strength of these considerations the appropriateness of the term "sequelae" for such manifestations of epidemic encephalitis has been called in question, and the term "residua" used in place of it. But the facts of the case are not so unique as to warrant this change in terminology. Seriatim nephritis is commonly regarded as a sequel of scarlet fever because an interval of a fortnight elapses between the subsidence of the fever and the appearance of the nephritis. But nephritis may also appear as a symptom of scarlet fever, and persist after the fever has subsided, yet no one has ever suggested on that account that seriatim nephritis should not be spoken of as a sequel of scarlet fever. The term "residua" may play quite a useful role as a label for the nervous syndromes that arise out of the acute phase of epidemic encephalitis and follow a subacute or chronic course of their own, but it can never displace the term "sequelae" for those syndromes which appear some time after the subsidence of the acute phase of the disease.

Age appears to play an important part in the incidence of the residua and sequelae of epidemic encephalitis. Psychomotor excitement, with or without nocturnal wakefulness and somnolence by day, tics, choreiform movements, and disorders of the respiratory rhythm, show a preference for the early years of life. On the other hand, the Parkinsonian syndrome, the well defined states of mental disorder—mania, melancholia, and confusion—and the residual paralyses are the appanages of youth and adult life.

Sex does not appear to influence the incidence of the sequelae, but there is some evidence to show that, although pregnancy does not play the part it was at one time thought to play in modifying the course of epidemic encephalitis in women, it influences the incidence of the Parkinsonian syndrome.

An attempt has been made to show that the severity of the acute attack influences the incidence of the sequelae. This is largely the work of observers who have been in a position to follow the after-history of patients whom they have treated during the acute phase. It is, however, a very common experience in a neurological clinic, or in a mental clinic for school children, to be unable to get a history of an acute attack of the disease in patients who show the sequelae of the disease in their most characteristic forms. This fact has led many observers to connect the incidence of the sequelae with the way in which the acute illness and the convalescence have been managed. These observers hold that the great desideratum is rest to the mind and body, and advocate six months of this for mild cases and a year for severe cases.

There is much evidence to show that the nature of the sequelae varies from epidemic to epidemic. Thus the Parkinsonian syndrome was a common sequel of the 1919 epidemic, and was practically unknown in that of 1918. On the other hand, psychomotor restlessness with nocturnal wakefulness was a common sequel of the epidemic of 1920-21 and athetoid movements of the epidemic of 1923-24.

## 3 The Mental State of the Restless, Naughty Child

A great deal of attention has been paid to the restless, naughty child because of the social and educational problems that he raises, and much that has been written about him is wide of the mark. The moral aspect of his behaviour has been emphasized, naturally enough, as it is his apparent

disregard of all moral considerations that makes him impossible at home, at school, or in the sick ward, and in my mind has seemed to be the most striking feature of his behaviour. I have often been asked to see him in his absence, and in my opinion of his moral sense. Strangely enough, very little has been said about the *mannal* character of his misbehaviour, although it has more affinity with that of the maniac than with that of the delinquent, hebephrenic or that *para avis*, the moral imbecile. There is nothing cunning or underhand about the misdeeds of the restless, naughty child. Unlike the delinquent, he does not choose a convenient season in which to commit his misdeeds, he carries them out in the public eye. He acts on the spur of the moment, and his offences are quite devoid of malice prepense. On the other hand, he does not show the stolidity of the hebephrenic or the moral imbecile. He is accessible to an appeal to his better self and is not insensible to correction. Most of the outrageous incidents in which he figures arise from injudicious handling. He commits some venial offence. Everything turns on the way in which he is corrected. If he is taken the right way the matter ends in tears but if his anger or resentment is aroused he throws the first thing that comes to his hand at the head of his censor, or indulges in all sorts of threats or abuse of him. But whichever mental state is aroused is of short duration and soon gives place to another. In short, there is any amount of instability, but little or no evidence of moral depravity, in the misbehaviour of the restless, naughty child.

If the mental state of these children be looked at as a whole, the instability that is so striking a feature of their misbehaviour is seen to be confined to no particular faculty of their minds. All their mental processes are unduly mutable. Their ideas, their moods, and the impulses of their wills are all easily induced and, failing to develop properly, are readily supplanted by others. In consequence of this these children become the slaves of their environment. They no longer behave according to the principles instilled into them by their upbringing, but obey the whim of the moment. They become pet and forward, inclined to tail to any person they meet, and to handle whatever catches their eye. Incidental and non-essential ideas, aroused by habit of speech or similarity of sound, break into their talk giving it a smack of piecemeal. On the other hand, their restlessness is far from aimless, it is well a piece of occupation. They are always busy about something, and so long as their activities can be confined to useful channels they work well under supervision.

What the psychologist calls *general intelligence* is not affected by the disorder to any appreciable extent. The recognized mental tests show that the apparent precocity of the restless, naughty child is not accompanied by a high intelligence quotient. On the other hand, it is quite exceptional for one of these children to have an intelligence quotient below 85. Nothing in the nature of a secondary dementia is ever seen, even when the disorder has lasted so long as nine years. All that may be said about them is that their mental powers do not mature. They are a sort of Peter Pan—they never grow up.

## 4 The Clinical Affinities of the Parkinsonian Syndrome

This sequel of epidemic encephalitis derives its name from the resemblance it bears to paralysis agitans. Although at the first glance the resemblance appears close, one, it does not stand detailed examination. There where an undoubted similarity exists between the two conditions there are important points of difference. There is, for example, no doubt about the strong family resemblance between the tics of Parkinsonism and Parkinson's mask, but the former shows none of the deep furrowing of the brow that is so prominent a feature of the latter. Again, there is much in common between the posture and gait that the patients manifest in the two conditions, but the localized distribution of the muscular spasm and the "kinesia paradoxa" that are often seen in Parkinsonism never occur in paralysis agitans. As for tremor, a symptom common to both conditions, it rarely dominates the Parkinsonian syndrome as it does paralysis agitans.

The differences which exist between the two conditions are notable. In the first place there is nothing in paralysis agitans comparable to the metabolic disturbances that often

constitute an important part of Parkinsonism. In Parkinsonism the skin of the face has not the thick, greasy look that it has in the faces of Parkinsonism, and it is never associated with sialorrhoea. Moreover, constitutional changes, such as are seen in the *forme ephrénétique* or in the tendency to obesity that patients suffering from Parkinsonism show, are never met with in paralysis agitans.

When cases of Parkinsonism begin to appear in France during 1919 they were often referred to as atypical cases of *l'atonie*. This identification of the characteristic sequelæ of epidemic encephalitis with *l'atonie* is in many ways more just than that implied in the term "Parkinsonian syndrome." So far as its somatic symptoms are concerned *l'atonie* has more in common with Parkinsonism than paralysis agitans. When well developed the faces of the two conditions are practically identical. Both show the stretched look with the smooth forehead, the thick greasy skin, and the saliva dribbling from the half-opened mouth. In both conditions the tongue tends to become small, indented, and the seat of an intrinsic tremor. The posture and gait are likewise very similar even to the presence in *l'atonie* of a condition in every way comparable to *kinesia paradoxa*. On the other hand epileptic manifestations which are a common feature in *l'atonie* rigidity, are sometimes seen in the rigid muscles of Parkinsonism. Here the resemblance breaks down for while mental changes are common in Parkinsonism the stolidity and inaccessibility of the *l'atonie* are never seen indeed it may be said that if a Parkinsonian were to become inaccessible *aprio facto* he would become a *l'atonie*.

## V—THE INDEPENDENCE OF BRADYKINESIA AND OF HYPERTONUS IN RESPECT OF PARKINSONISM

BY  
PROFESSOR RENE POUCHET M.D.,  
Bordeaux

THE polymorphism of epidemic encephalitis or encephalomyelitis which we distinguished in 1917 in describing for the first time this hitherto unknown disease is no longer under discussion. This is the principal reason why Professor Luriers, dean of the Faculty of Medicine of Montpellier recently said that there is no better name for this disease than the name of the author who first described it.

Of the many different aspects of the disease I will consider only a single point which I mentioned in my London lecture on the bradykinetic syndrome in 1925. Many authors admit that the slowness of movement in post-encephalitic Parkinsonism as well as in Parkinsonism in general is an effect secondary to the peripheral muscular hypertonus. So understood bradykinesia should be but a simple and particular case of movements which are executed against resistance. This point of view could

Graph showing the normal postural reflex. S Passive response of the tendon of the tibialis anterior produced by flexion of the foot. R Reflex. L Relaxation time of postural reflex.  $t_1-t_2=2.5$  seconds.

not be maintained and may fail to show perfectly the independence of bradykinesia. For a long time Vejer and I have noticed the existence of sequelæ of encephalitis which are characterized only by slowness of movement without real muscular hypertonus in such patients the postural reflexes and tendon reflexes are quite normal. It is not rare to discover hypertonus in such patients after several months. It is ordinarily of the type of Parkinsonian hypertonus characterized by exaggeration of postural reflexes. We call by that name the postural reflexes described by Forst and Thénard also called by Delmas-Marsalet elementary postural reflexes.

The simplest way of eliciting the reflex is to place the foot in flexion on the leg which renders evident the postural reflex of the tibialis anterior. This is obtained

a graph which can be resolved into three parts. The first part (S) indicates the passive response of the tendon of the tibialis anterior to the flexion of the foot. The second part (R) represents active contraction of the tibialis anterior—that is to say the real postural reflex. The third part (L) the foot being left alone indicates the return of the foot to its initial extension or position. This return takes a certain time (indicated on the graph by  $t_1-t_2$ ) which is called the relaxation time of the postural reflex. The duration of this relaxation time varies according to the greater or less intensity of the postural

Graph showing the action of Scopolamine Injection on the Postural Reflex of a Case of Encephalomyelitis (Anterior Tibialis)

Before injection Relaxation time of postural reflex  $t_1-t_2$  = 2 seconds.

Twenty minutes after injection  $t_1-t_2=2$  seconds

Twenty five minutes after injection  $t_1-t_2=11$  seconds

Thirty minutes after injection  $t_1-t_2=4$  seconds

Thirty five minutes after injection  $t_1-t_2=2.5$  seconds

Forty minutes after injection  $t_1-t_2=1.5$  seconds

Forty five minutes after injection Absence of the postural reflex and persistence of bradykinesia

reflex. Normally it is as shown on the graph. Lastly, with old Parkinsonian cases hypertonia can be transformed into a pyramidal type characterized by ankle clonus and Babinski's sign.

Whatever the type of case and whether the patient is not hypertonic or his hypertonia is a Parkinsonian or a pyramidal one bradykinesia remains exactly the same. This clinical observation therefore, shows well the independence of bradykinesia and the variable state of the muscular tonus.

These facts undeniable from the clinical point of view, needed an experimental demonstration. This has just been

given by one of my pupils, Dr Delmas-Marsalet. His test is as follows. By subcutaneous injection a solution of scopolamine biomhydrate is given, this provokes in Parkinsonians a progressive abolition of postural reflexes, which is complete in about forty-five minutes. It is well seen in the accompanying curves. At the moment when the scopolamine injection has completely abolished the postural reflexes, different segments of the limb are in flaccidity, and there is no longer hypertonia.

It is most important to note that if the patient is asked to execute movements these remain distinctly slow, in spite of the disappearance of hypertonia. What is equally remarkable is that the abolition of postural reflex leaves the tendon reflex and general sensitivity completely intact. It even permits, when pyramidal excitation and Parkinsonian hypertonia are associated, the reappearance of pyramidal excitation (clonus of the knee and ankle, and exaggeration of the patella reflex), which this hypertonia had inhibited.

These different facts indicate clearly that it is useful to separate bradykinesia from hypertonia. Bradykinesia, just as much as bradyphasia, must be considered as an alteration of special nervous functions which have nothing to do with the tonus. It seems that bradykinesia represents, as Vergé has said, a deficit of a general function of the brain—the automatic habit function.

Delmas-Marsalet's test in experimentally isolating the postural reflex gives a rational explanation of the action of scopolamine, known for a long time in Parkinsonians, and of the irregularity of this action. With the ordinary bradykinetic patient, without postural hypertonia, the effect of scopolamine is only moderate, the best result is obtained with the bradykinetic with postural hypertonia. When this condition is complicated by pyramidal signs the result is bad, because the abolition of postural reflexes will increase the pyramidal contracture still more. It is only in the cases in which pyramidal contracture, clinically absent, is discovered by the scopolamine test that the result is good, if this contracture is slight, it is right to use scopolamine. If this contracture is strong, it is better not to employ it.

#### DISCUSSION

Professor GEORGES GUILLAIN (Paris) said that at different periods in the evolution of chronic epidemic encephalitis, soon after the onset of the disease, or a long time after the development of a Parkinsonian syndrome, it was not exceptional to observe symptoms which resembled those of myasthenia. When they were localized only to the limbs, or to isolated groups of muscles, the diagnosis of myasthenia gravis did not occur to one, in more numerous cases, however, the myasthenic symptoms, beginning in muscles supplied by mesocephalic nerves and later becoming generalized, revealed a clinical picture identical to that of the Erb-Goldflam syndrome. In such cases either a history of typical acute epidemic encephalitis before the onset of the condition, or certain symptoms of the Parkinsonian syndrome, indicated the true nature of the myasthenia. Th. Alajouranne and he had described such cases, and recently A. Wimmer (Copenhagen) had recorded a series of similar observations. Professor Guillain wished to recall the characteristics of the myasthenic aspects of epidemic encephalitis, and gave notes of three cases which disclosed three different aspects of abnormal myasthenic syndromes. The first two closely resembled myasthenia gravis, in the first a Parkinsonian syndrome, in the second a recent epidemic encephalitis, demonstrated the infectious etiology of the myasthenic syndrome. In the third case (seen at the Salpêtrière with Dr Thévenard) the clinical picture was partly that of an alternating syndrome of the bulbo-pontine region, and partly that of myasthenia, according to the character of the parietic troubles and their variability. The history of the disease and the influence of sodium salicylate treatment again suggested

the encephalitic etiology. Encephalitis lethargica seemed, therefore, able to produce symptoms quite similar to those of myasthenia. And furthermore, in encephalitic sequelae it was not exceptional to meet with isolated myasthenic symptoms, which were absent in the clinical picture of a Parkinsonian syndrome. Such cases were interesting from the point of view of diagnosis and prognosis, they did not seem to evolve progressively and severely as did myasthenia gravis. The diagnosis, too, was made easy by the knowledge of an acute period of infection or by the observation of sequelae of encephalitic type. Mean while certain cases could offer difficulties in their interpretation. In such cases the electro-diagnosis did not give any real help, but with Bourguignon's technique the study of chronaxy would give new reasons for supposing an encephalitic etiology. This series of observations showed the great variability of syndromes depending on encephalitis, and allowed a new conception to be formed of the still obscure etiology of myasthenia.

Dr E. MATHOTER (London) said that the psychiatrist was rarely concerned with the acute phase of encephalitis, and neither its intensity, type, nor duration seemed to be correlated with the severity or character of the mental sequelae. He quoted cases indicating how spurious psychogenesis and lack of physical examination might lead to cases of encephalitis being regarded as functional psychoses and neuroses. Febrile attacks, which were apparently a recrudescence, occurred in cases with mental sequelae, and sometimes led to increase of these, and also favoured the idea of continuing infection rather than maladjustment to damage done during the acute stage. Mental sequelae were almost independent of neurological syndromes, and this pointed to their dependence on lesions in special foci or systems of neurons. The attribution of delinquency to infection before a stable ethical code had been organized was obviously inadequate, since it occurred in those who had been normal adults, it was clearly a regression, not merely an arrest. No "moral centre" need be postulated but derangement of levels that subverted foresight of consequences—a view that was supported by indifference to danger in some of the same patients. This point was of great theoretical importance in relation to "moral imbecility" and cases of demoralization after head injury. Dr Marshall's identification of restlessness and delinquency seemed very questionable, often the occasional delinquent was perfectly quiet. The restlessness of the post-encephalitic differed greatly from the joyous excitement of true mania. With Parkinsonism mania was rare but suicide was common, this might be sense or insanity, but not euphoria. Lastly, the resemblance of katatonie to Parkinsonism was no greater than that of functional hemiplegia to organic, and the difference of the same order. The one was mental and the other not—doubtless a difference of level, but a material one. They could usually be simply distinguished clinically. The disabilities of the Parkinsonian were mainly in automatic activity, co-operation was ready and effort reduced disability. The usual immediate effect of urging the katatonic or hysterical to effort was increase of disability.

Dr B. SACHS (New York) said that following the European epidemic of 1918 the first cases were seen in New York in the winter of 1918, and were reported upon early in 1919. While there had been marked variations in the number of cases seen in succeeding years, the disease had been steadily with them in New York, both in its acute form and especially in its sequelae. Dr Sachs wished to supplant "encephalitis lethargica" by the term "central and basilar encephalitis"—which it really was. He used the term in his own writings. The history of the disease as it occurred in New York, and as reported in the volume published by the American Association for Research in Nervous and Mental Disease in 1921, tallied in every way with the account given by Dr McKenzie of Glasgow. In later years the myoclonic and choreic symptoms were much more marked than in the earlier years. There was no doubt a gradual attenuation of the virus, and probably some change in the site of the lesion. The motor manifestations of the disease, with frequent involvement of the basal

gingling had gained a special importance with reference to the more recent studies of the functions of the corpus striatum. Ramsay Hunt favoured the conception of two striated systems—one for the control of the automatic and associated movements (the pallidum system) and the other for inhibitory and co-ordinating functions (the neo-striatal system). Interference with these functions was responsible for the symptoms resembling on the one hand those of paralysis agitans and on the other those of chorea or athetosis. When both systems were involved there might occur any possible combination of the two types of motor disorder. Some of the lesions in the acute infantile cerebral palsies might be of cortical origin but these infantile cerebral palsies were sometimes of ganglionic origin. Dr Sachs was in full sympathy with Dr Marshall's report on the mental aspects of this epidemic disease and would particularly wish to endorse what Dr Marshall had said about the mental state of the restless naughty child but again he was still more impressed with the recollection of these adult cases of the disease that began with psychic symptoms (in one case a very unusual frictionsness, suggesting frontal lobe involvement) very acute manic symptoms and in several instances were fatal within two weeks. Some might stop to think of the cases of chorea in children of years ago so often fatal. There was also general agreement on the conclusion that epidemic encephalitis and acute poliomyelitis were distinct clinical and bacteriological entities in spite of the contention of Neustädter, Turkin and Baurthal that they were able to neutralize the poliomyelitis virus *in vitro* in six instances with serums of patients recovered from epidemic encephalitis and completely protect the six monkeys experimented upon. Amos (1921) stressed the point that experimental poliomyelitis is readily transmitted while epidemic encephalitis could not be transmitted experimentally with anything like the same ease.

Professor Karl Pribram (Umeå, Sweden) said that two Swedish observers, Professor Sjogvall and the late Professor Forssner had shown that phlogocytosis was invariably present in poliomyelitis during the acute stage and was of great importance in explaining the destruction of the motor cells. These findings had been amply confirmed by later authors. On the other hand in encephalitis lethargica phlogocytosis was usually entirely absent. These differences were in accord with the divergent courses of the two diseases. In poliomyelitis the paralytic symptoms reached their maximum intensity in a few days—almost always in not longer than four days. In contrast his difference was the course of encephalitis lethargica, a fact that it was not necessary to emphasize. Professor Petren also called attention to the oculocephalic reflex of Guillian in the diagnosis of the Parkinsonian state. This reflex consisted in the exaggeration of the blinking of the eyelids elicited by tapping the skin about the root of the nose. Professor Petren had found this reflex invariably present in the Parkinsonian syndrome. Dr Riddell had mentioned that there was often a certain interval between the acute phase of encephalitis and the appearance of Parkinsonian phenomena. It was therefore a question of the highest practical importance to determine how long this interval could be or in other words how long after a patient had had encephalitis lethargica might a Parkinsonian syndrome follow. In a large experience of such cases Professor Petren had never found this interval to be longer than four years.

Dr W. A. Potts (Birmingham) challenged the statements that the disease had a tendency to pass definite course and that the anatomical damage was permanent. For a long time there was numbing rather than destruction of the higher and other special brain centres. Such a conception was a better explanation of many cases especially the not infrequent ambulatory type. So far from not resembling neurological syphilis it was similar in many ways especially in still being amenable to treatment if thorough and prolonged even in late stages. There was also a choice of at least two possible courses according to the temperament and mental outlook of the patient—namely (1) the path of the dementia praecox type in which all its varieties showing almost continuous abnormality and (2) the path of the manic-depressive type

alternating between the euphoric (manic) state and the depressed state with lucid intervals for weeks often for months and sometimes for years. In connexion with the diagnosis there were two important symptoms. The first was the fact that in the ambulatory case when the patient did not leave his work for more than a day or a week-end there was always a history of at least two or three hours during which he felt desperately ill. The second was the fact that while in the later stages there was no loss of intelligence there was always in children a failure of other mental faculties to develop and sometimes an actual regression. In the adult the corresponding feature was a diminished sense of responsibility the result of which was bizarre or immoral conduct. Dr Potts advocated a course of autogenous vaccines or non-specific protein therapy with investigation of the teeth and thorough investigation of the intestinal tract which sometimes might be nothing less than a long course of Plombiere's colon douching. Each symptom must be treated as a further indication of a septic psychosis not yet completely dealt with. It must be remembered that while the most important fundamental factor was the unhealthy state of the alimentary tract and the unsatisfactory diet it was necessary to consider the probable entrance of the infection from the nose through the cribriform plate of the ethmoid hence the frequency of ethmoidal sinusitis as a complication, and the fact that the majority of early signs came from the base of the brain. The first step in treatment should be thorough disinfection of the nose itself this could not be effected by the occasional use of a watery application, but only by the daily and prolonged use of an oil solution of an efficient coagulating antiseptic to prevent further infection by the original virus or any secondary germs.

Dr Julian M. Wolfson (San Francisco) regretted that treatment of the chronic encephalitis had met with such poor results. Many chronic cases could be prevented by paying more attention to the acute stage of the disease. He had been his experience that few cases of the disease in its acute stage passed into the chronic stage if no matter how slight the symptoms were mental and physical fatigue were absolutely interdicted for six months once the case had been diagnosed as lethargic encephalitis. The management of the acute case after fever had subsided included complete rest intestinal antisepsis and administration of polyvalent autogenous vaccine from the intestinal tract and nasopharynx.

Dr T. A. Ross considered that 'neurasthenia' was a real entity as anything in medicine. The history sought for was a biographical one to indicate how the patient reacted to the ordinary difficulties of life at all times. The failure to regard 'neurasthenia' positively and not merely negatively had caused it to be considered as a sort of rubbish heap from which people were always extracting new diseases.

Dr Potton (Oldham) said that Parkinsonism in our appearance in the early stage was centrally a derangement of posture. He mentioned two cases the first of which showed a spasmodic cramp of the upward glance and indication of one a subacute excitement which was induced by postural position and which rested upon the entire controlling movements. The second case was one of complete external ophthalmoplegia with diplopia or six months standing. Simple swinging of the ears with cold water enabled the patient temporarily to move his eyeballs in every direction and caused the diplopia to disappear. These and other findings led the speaker to argue that a vestibular in not only existed but that it was responsible for the commonest group of symptoms—namely the ocular manifestations.

Dr P. C. Lower (Birmingham) considered that the mental symptoms of encephalitis lethargica were of the toxic infective type and resembled in some features the acute mental effects of such toxins as klonal because neurotoxins depolarized all nerve cells and especially those of the highest levels. In encephalitis in addition to the severe local lesions there was evidence of a depression of higher cortical functions in the characteristic organic

mental reaction of lethargy and the weakened attention and "gasp", Dr. Greenfield had shown that there might also be visible evidence of cortical cell degeneration. The mental changes could best be understood by utilizing the conception of "neuronal energy," and thinking of mental and nervous phenomena as evidences of orderly evolution and distribution of energy derived from the activity of the neurons at different levels in the nervous system. Heid had observed that the decerebrate cats of Buzzett and Penfold responded to stimuli reflexly and purposefully, so that a drop of water placed in the ear led to shaking of the head, while touching the ear with a finger produced a different but appropriate response. This purposeful adaptive character of reflex response to stimulation was only seen when the internal and external environment of the animal was good and the nervous system was said to be in a state of "vigilance"; it was abolished temporarily, for example, when the cat was given a little chloroform or suffered from sepsis. By considering what "vigilance" implied physiologically and applying that conception to high cortical levels, a close parallelism would appear between high vigilance in the cortex and high mental efficiency, with its heightened attention and ability to respond appropriately to whatever stimuli might arise in the changing environment of the individual. Attention implied in psychology largely what "vigilance" did in physiology—namely, that condition of the mind (nervous system) in which a selective response to a stimulus could be obtained at its optimum. It was these psychic characters which were impaired in mental disturbances of toxic and infective origin. Hence arose lethargy, defective power of concentration, loss of interest, and the inability to organize reactions according to social standards which characterized the child suffering from encephalitis lethargica and head injury, possibly the same accounted for the asthenic syndrome described by Dr. Riddoch.

## OPTIMAL RHYTHM IN THE MAMMALIAN HEART AND THE ACTION OF THE CARDIAC NERVES

BY

J. A. MacWILLIAM, M.D. F.R.S.,

Regius Professor of Physiology in the University of Aberdeen,

AND

G. SPENCER MELVIN, M.D.,

Professor of Physiology in Queen's University, Kingston, Canada

(From the Physiological Laboratory, Aberdeen)

Under experimental conditions, with the influence of anaesthetics, etc., the mammalian heart muscle shows two distinct types of behaviour, in which the ventricular contraction force is very differently influenced by changes in the rate of beat, whether such changes are then owing to local alterations in the normal pacemaker, to artificial or normal excitations, or to the influence of the cardiac nerves. In a communication to the International Physiological Congress in 1923, these types were designated I and II. Cats and rabbits were employed, anaesthetized with chloroform, ether, methane, etc., or decerebrated during anaesthesia with chloroform and ether. Graphic records were made from auricles and ventricles by the Canny myocardiograph or by an optical form. Intracardiac pressures, etc., were also registered in many experiments.

### CHARACTERISTICS OF TYPES

In Type I, which is the normal, premature or much accelerated beats tend to be of diminished force, while delayed beats, as seen after a compensatory pause or during simple slowing of rhythm, usually tend to be stronger. Within limits, the longer the interval between beats the longer is the ensuing beat. The optimal interval is indefinitely long. In Type II, on the other hand, there is a certain range of interval which is approximately optimal regarding contraction force. Slowing leads to weakening, the degree of which stands in strikingly close relation to variation in the length of the intervals. Acceleration beyond the limits of the optimal rate is attended by reduced

size of beat. The optimal rate varies under different conditions, it may be very much higher than the ordinary heart rate of the animal—in the cat, with its normal 90 or 100 beats a minute, the optimal rate may be 200 to 240—about the maximum rate of the heart after section of the vagi.

Sudden changes between periods of optimal and sub-optimal rhythms are attended by sudden diminution or augmentation of the beats. Similarly, single beats following an optimal or suboptimal interval show immediate and striking differences in size, not depending on changes in blood pressure, but connecting a special metabolic condition of the ventricular muscle in which recovery after a contraction is rapid and is followed by early return in contraction power, if another excitation does not occur after an interval of such duration as is suitable or optimal in the particular conditions of the muscle at the time. The behaviour of the contraction force is similar in ventricular beats due to excitatory impulses arriving from the auricles in normal fashion through the auriculoventricular bundle and in beats provoked by artificial stimulation of any part of the ventricular muscle.

The phenomena in question are related to what has been described as a "supernormal" phase in nerve and cardiac muscle of lower vertebrates under certain conditions. But the enlarged ventricular beats are not really supernormal, their increased size represents a return to or towards the normal from a subnormal size, which had been determined by the presence of a suboptimal rate of succession with intervals long enough to lead to a decline of contractile power below the optimum.

### DISTRIBUTION AND CHANGE OF TYPE

Type II has been seen only in the ventricles, where in a long series of experiments extending over many years it has been found to be about as common as Type I in cats. In rabbits, on the other hand, under similar experimental conditions, Type I was always recognized. The auricles of all the animals examined (cats, rabbits, etc.) always showed Type I. Repeated changes of type were often observed in the course of a single experiment. Type I is frequently altered to Type II after a phase of asphyxia or intravenous injection of adrenaline, alone or after a depressing dose of potassium, etc. Type II is often replaced by Type I after the administration of pilocarpine, acetylcholine, and other drugs. The alterations in size of beat shown by the recording lever are not dependent on altered physical conditions—for example, blood pressure, or filling of heart.

### RELATION TO ACTION OF CARDIAC NERVES

Since slowing may *per se* cause weakening of the ventricular beats in Type II and acceleration may give marked augmentation, the question arises as to how far the effects of stimulation and section of the vagus and sympathetic nerves may be conditioned by simple rate changes in the heart under experimental conditions.

### The Vagus

The records show that pronounced ventricular weakening during vagus stimulation is sometimes capable of being accounted for solely by the associated slowing of rhythm resulting from the action of the nerve upon the pacemaker. During the period of slowed weakened beats a contraction excited at the optimal interval is of full size, in contrast to the greatly weakened preceding and following beats which have come after an unduly long (non-optimal) interval. But, on the other hand, there is frequently evidence of a direct weakening influence also being exercised by the vagus—the reduction in force being specially at the culminating part of the vagus period—out of proportion to the degree of slowing. There is thus a combination of rate effect and direct force depressing vagus influence.

In Type I the vagus can show marked weakening effects in the ventricles (as well as the auricles). Here, though associated with slowing of rhythm, the weakening is not directly due to the slowing. Simple slowing, from vagus influence on the pacemaker, apart from a direct force-depressing influence of the nerve, usually leads to enlargement of the slowed beats. When weakening is marked it bears no constant relation to the length of intervals.

between the beats. During *vagus* standstill or slowing and weakening a rhythmical series of artificial excitations calls forth beats showing a progressive increase in size (stature) this indicates an influence inimical to the force-depressing power of the *vagus* on the ventricular muscle. The actual effect of the *vagus* on contraction force depends on an interaction between the influence of rate changes and the direct force-depressing power of the nerve. In opposition to the current view that the *vagus* has no direct effect on the contraction force of the mammalian ventricles, the present investigation affords abundant evidence of strong weakening effects in exceptional instances more extensive than those seen in the auricles. The weakening action of the *vagus* on the ventricles differs in certain important respects from what holds good in the auricles, being differently conditioned by rates of beat etc. In the auricles *vagus* weakening may occur without any change of rate and acceleration (by artificial excitations) of slowed and weakened auricles does not produce the augmenting effects seen in the ventricles.

#### *The Cardiac Sympathetic*

As regards sympathetic action it is clear that the acceleration induced may in Type II determine marked augmentation in the ventricle. But it is plain that such is not the sole mode of action of the nerve, for the augmentation may be much greater than results from simply bringing the heart rate to the optimum frequency level. A further augmentation may be obtained by sympathetic stimulation while Type I is present in both ventricles and auricles. Hence rate change is only a possible contributory factor in the ventricles in Type II. There is a further specific influence beyond the direct effects of rate changes in the case of stimulation or section of either the cardiac augmentor or the inhibitor nerves and operative on both the auricular and the ventricular contraction force.

## THE MECHANISM OF VOLUNTARY MUSCULAR FATIGUE

BY

CHARLES REID, M.A. AND D.Sc.

Lecturer in Experimental Physiology in the University of Aberdeen

(From the Physiological Laboratory.)

THE present inquiry deals with two forms of fatigue in man: (1) that induced by a series of voluntary contractions of the flexor digitorum sublimis recorded by a Mosso's ergograph; (2) static contraction of the same muscle maintaining weights at certain levels and registered in the same way. Animal experiments (under anaesthesia) were also performed: the tibialis anticus of the rabbit and cat being used in contraction against an elastic resistance was registered graphically under different conditions. The relation of experimental ischaemia to the incidence and characters of fatigue were examined both in the human subject and in animals.

#### *Fatigue from Serial Voluntary Contractions*

When fatigue results from a series of voluntary contractions the failure of effective muscular response is primarily "central"—that is it is primarily due to defective outgoing motor impulses from the central nervous system. This is shown by the fact that further muscular response can still be obtained from electrical stimulation of the median nerve or of the muscle directly by single induction shocks, or by faradic currents at rates of 40 to 200 per second. But though the fatigue is primarily central it is not always wholly so, there is evidence of marked depression of contractility in the muscle itself at least when fatigue is induced by a very rapid series (for example, 120 to 160 per minute) of voluntary contractions especially when the weight raised is considerable—for example,

2 kilos. Here there is an overlapping of central and peripheral changes. On the other hand, when a slow series (40 to 80 per minute) of voluntary contractions is employed to produce fatigue the muscular response to direct electrical stimulation may be practically unimpaired at the point of time when voluntary effort fails to raise the weight, the failure is almost wholly central in this case.

The comparative effects of electrical excitation of the nerve trunk and of the muscle directly do not afford evidence of any marked selective influence of fatigue on the field of conjunction of nerve and muscle—the myoneural junction. The power of the contractile response obtained from (a) the nerve trunk and (b) the muscle directly stimulated shows little difference even in advanced fatigue involving a great diminution of the available muscular energy. For example in a rabbit's limb with intact circulation there was only a slightly greater response from (b) after about 50,000 contractions (pulling against an elastic resistance) had been executed in a period of four and half hours with reduction of the excursions to less than one-tenth of their original size. Such results are opposed to the hypothesis that comparatively early failure of transmission through the junctional region between nerve and muscle plays an important part in the genesis of voluntary fatigue.

Some previous observers have stated that after fatigue has been induced by direct electrical stimulation voluntary effort can still cause effective contraction. In the present inquiry it has been found that after thorough fatigue has been induced by local stimulation voluntary impulses fail to elicit any marked further contraction.

#### *Fatigue in the Ischaemic Condition*

In the ischaemic arm muscular fatigue from a series of voluntary contractions occurs much more rapidly than in the normal limb—for example in two to three minutes as compared with fifteen to twenty minutes. The direct depressing effects of the bloodless condition on the working muscle might be supposed to account for this but it is found that local excitation (median nerve or body of muscle) still gives a marked though reduced contractile response. The fatigue is primarily in the central nervous system in this case also, weakening of the muscle develops as well though much more slowly than the voluntary failure.

Why should central failure occur much more readily here than in the limb with normal circulation since the central nervous system is far removed from the ischaemic area and beyond the reach of chemical agents metabolites etc., transmitted from the ischaemic limb? It is evidently contingent on afferent nervous impulses from the working muscle depending on conditions set up in it by repeated strong contractions—conditions (chemical etc.) naturally accentuated in the bloodless muscle setting up painful afferent impulses much more rapidly than in the normal arm.

Ischaemia *per se* cannot be regarded as the cause, for with quiescent muscle ischaemia up to a duration of fifteen minutes produces no discomfort and has no appreciable influence on the power of voluntary contraction. From the much earlier failure of response to voluntary effort during ischaemia it is evident that local conditions in the working muscle form part of the mechanism of fatigue. But the central nervous system is also involved, since further contractile response is given to local stimulation after voluntary effort has failed. The "central" failure is not simply a primary or direct one affecting some part of the central nervous mechanism concerned in voluntary motor discharge but is largely a reflex effect of afferent impulses from the working muscle—no doubt protective against excessive prolongation of activity and undue development of fatigue in the muscle.

Thus the conditions of developing fatigue arising primarily in the working muscle do not directly induce the depression of contractile power shown in the ergograph records. Their influence is exercised in reflex fashion by afferent impulses concerned in producing the "central" failure which determines the ineffectiveness of voluntary effort (in both normal and ischaemic limbs).

at a point of time when there is still much contractile energy available in the muscle if effective motor impulses were provided. There is reason to regard the process of fatigue in the ischaemic limb as similar in most respects to what occurs with the intact circulation, though more rapid and acute.

#### Static Fatigue

The onset of failure in this form of fatigue is of central origin, since when the continuous voluntary effort can no longer sustain the weight and prevent the shortening of the muscle from being overcome, the muscle can still respond strongly to direct electrical excitation. In this respect there is a general resemblance to the fatigue induced by a moderately slow (40 to 80 per minute) voluntary series of contractions. But in some other respects the two forms differ strikingly—for example, in relation to the influence of ischaemia.

The length of the period during which voluntary effort is effective in maintaining static contraction is very little affected by an ischaemic condition of the limb; indeed, the curves obtained in the normal and in the ischaemic states may be almost superimposable—in notable contrast to the rapid development of failure in voluntary serial contractions in ischaemia. Again, a period of static contraction has an improving effect (on contraction force), less than that of a period of rest, when interposed in the course of a series of voluntary contractions showing the progressive development of fatigue. There are indications which point to static fatigue with intact circulation as being essentially due to fatigue in the central nervous system, not dependent in any important degree on afferent impulses from the contracted muscle so far as evidence is available.

#### THE PINEAL GLAND \*

PROFESSOR HERMINE (St Andrews) showed a series of lantern slides illustrative of the histology of the pineal region of the mammalian brain. It was pointed out that the pineal body was not the remnant of the pineal eye found in some of the lower animals. The pineal body was a separate structure which was developed behind the pineal organ or pineal eye. In man and most mammals the pineal body was bound up with the habenular and posterior commissures, but in the rat the pineal body lay on the surface of the brain between cerebrum and cerebellum. In the animal it was isolated and highly vascular body which was suggestive of an organ of internal secretion. The pineal body of the rat was innervated only by fine nerve fibres, which entered it with the blood vessels. The mammalian pineal body contained a material which produced contraction of the myonophores of the tadpole, but its function was as yet unknown. Attention was drawn to the subcommissural organ of most mammals, which Dendy regarded as a receptor brought into action by changes in tension of the fibre of Reissner. The organ was well developed in most mammals, but was rudimentary in man.

#### PROTEIN METABOLISM IN CYSTINURIA \*

PROFESSOR D. MURRAY LION and MR. W. ROBINSON, D.Sc. (Edinburgh), in a joint contribution stated that various aspects of protein metabolism in a case of cystinuria had been studied. Cystine added to the diet to the extent of 20 grams over a period of four days was found to be quantitatively oxidized to inorganic sulphate. Likewise other amino acids were found to follow the normal paths of metabolism and to lead to increased water excretion. Addition of sodium bicarbonate caused an increased output of cystine, practically the whole of it being in solution in the urine and only a small part in the urinary sediment. Disodium phosphate had no appreciable effect in producing the alkalinity necessary to hold in solution the cystine excreted. Changing the diet to one containing more protein gave rise to an increased excretion of cystine. The position of the "inborn error" was discussed.

#### MODES IN WHICH DRUGS HAVE BEEN INTRODUCED TO USE

BY

WALTER T. DILLING, M.B., Ch.B.,  
Associate Professor of Pharmacology and General Therapeutics,  
University of Liverpool

THE early history of the introduction of remedies is closely interwoven with the origins of primitive religions and, while reserving judgement on the theory that some animals have a crude idea of "first aid," it is highly probable that, since man's continuous effort has been to overcome the obstructions of Nature to his welfare and progress, his selfish instincts must have led him to seek means of defence against his personal injuries and diseases even before he evolved a communal religion.

The customs of primitive tribes show that the etiologies of diseases and misfortunes were first ascribed to malevolent human agencies, then to the interference of demons, and, progressively as religious beliefs developed, to infringement of a taboo, to neglect of ancestral spirits, and, finally, to an offended deity.

Among the least cultured peoples treatment commenced as a magical rite or exorcism, associated with the external application or internal administration of some medium, this medium or "drug" was essentially an amulet aiding the protection of the individual or the expulsion of the demon, in Polynesia, for example, the medicine given was "considered more as a medium by which the god would act than as possessing any power itself to arrest the disease."

When these primitive rituals had as objective the benefit of the individual they became the basis of primitive therapy, but when they had as purport the protection of the community from pestilence, famine, or other calamity, they became the foundations of religious belief or of public hygiene in the tribe.

As diseases became differentiated so the number of etiological demons multiplied, thus, there were evolved specialist medicine men and an expanding list of exorcising remedies of specific purport, in other communities exorcism or propitiation of several demons or deities was attempted by repetition of the magical rite or by numerical grouping of the remedies or the times of their administration.

A typical instance of this phase is recorded by Rivers at Iddystone Island, where epilepsy is treated by stroking the patient with four leaves and calling on "four ancient women" of the tribe, the treatment being performed on the last four days of the waning moon and repeated after four months. This case shows the primitive use of herbs purely as amulets, associated with the numerical arrangement of the rite and the herbs to influence four etiological factors, and indicates a primitive belief in the influence of the satellite on epilepsy.

Early Vedic literature provides confirmatory evidence of these views, thus, in the Atharva-Veda (circa 1000-700 B.C.), treatment is uniformly magical in type and curative agencies are amulets, the exorcisms may be directed against a human sorcerer or demons, or an offended deity is propitiated. The remedies were chosen on religious or mythical grounds, thus, butter and the soma plant were of great holiness, lead, catechu, colocynth, cinchona, and mustard had potent demon-dispelling powers, while cinchona was used for jaundice because of its yellow colour—a type of sympathetic magic. Liquorice was a charm to secure the love of women, and incense was a component of a battle charm. In Zoroastrianism also drugs were utilized chiefly as charms to expel demons.

Although there is some evidence, both from the primitive tribes in the Philippines and in America and also from the classical period, that drugs were tested upon animals and sometimes upon man, the evidence from primitive medicine regarding the evolution of drugs is against experimental therapeutics and in favour of the opinion that they were originally used for driving out the demons of disease from the body, hence we find in primitive therapy a preponderance of remedial measures having effects as purgative,

\* Read in the Section of the History of Medicine at the Annual Meeting of the British Medical Association, Edinburgh, 1927.

emetics, anthelmintics, etc., and of physical means such as bleeding, cupping, counter-irritation, and massage. Comparative physiology also supports this contention by affording proof that in many languages the root which implied "magic" or "incantation" produced stems to which were applied the transferred meanings of medicine—remedy, poison or physician.

As however diseases became clinically defined experience proved the empirical advantage of certain herbs or formulae. Two probabilities now arise: (1) the use of the drug might be continued while its magical rite was discarded, or (2) the symbolic ritual might be preserved—especially through folk medicine—and the remedy become obscured by admixture with others. This transitional phase is illustrated in Assyro-Babylonian tablets.

Our knowledge of Egyptian civilization affords proof that even in the first to third dynastic periods it was possessed of co-mesic pomades and paints, but the earliest medical treatises—the papyri of Ebers, Hearst, Smith, London, etc.—are all from a period approximating 1500 B.C. which may be regarded as a climax of Egyptian therapeutics. The Egyptians had on the evidence of the Ebers Papyrus at least, largely discarded the incantation, but this papyrus contains many prescriptions consisting of four remedies which are to be given on four occasions. The numerical grouping is evidently an endeavour to propitiate the four sons of Horus who guarded the four corners of Heaven and who presided over specific organs of the body; here we have an origin of the doctrine of physical and physiological fours. The Ebers Papyrus was a temple formula, which it was scrupulous to amend, but the priest-physician might record against prescriptions of proved value the words: "Good to use. It shows therefore a break away from theurgy and an attempt to establish empiricism. The formulae are difficult to work, partly because of unidentified ingredient and partly because the active ingredient is rarely placed first. In assuming that some of the formulae gave a measure of effective result, there is reasonable ground for believing that we owe to the Egyptians an elementary pharmacology of the following remedies:

*Emetics*—Copper salts, squill.

*Purgatives*—Figs, dates, raisin, aloes, ricinus oil, sea-salt, artemisia.

*Carminatives*—Caraway, coriander, juniper, myrrh, mentha (*P. pulgium*), fennel, dill, onion.

*Astringents for Dysentery*—Lead salts, egg albumen, gruel.

*Worms*—*Ascaris*, Pomegranate root bark, artemisia, ricinus seed, sea-salt, copper subacetate, *Taenia*, Ricinus seed, artemisia, mentha, lead salts, sea-salt.

*For Diarrhoea* (hookworm)—Turpentine resin, artemisia, mentha.

Meat and lincseed were used to make poultices, and to these were added herbs containing volatile oils which would act as counter-irritants for wounds, poultices containing sea-salt, onions or aromatic herbs, and wine are advised while conjunctivitis was treated by salves containing metallic astringents—for example, salts of lead or copper. Juniper and sea salt occur frequently amongst diuretic prescriptions. Other drugs, of which the purpose is obscure, are opium, poppy capsules—possibly also the juice—hosecramus, hemlock, zinc oxide, and iron sulphate.<sup>10</sup>

There is no doubt that the knowledge of Egypt filtered through to contiguous nations, and Assyro-Babylonian tablets dating from about 600 B.C. when the Assyrian physician had not succeeded in divorcing medicine from magic contain recipes which may be grouped into two types—older forms redolent of exorcisms and newer forms which are simply prescriptions. Assyrian remedies which have not been clearly established in the Ebers Papyrus are sulphur for itch, attar of roses, bitumen, almond oil, galbanum, gum liquorice, and amse.<sup>11</sup>

In Brahminical therapy a great improvement occurred between Vedic time and the Charaka-Susruta period (circa first to fifth century A.D.). Accumulated experience enabled Charaka to evolve fifty groups, each containing ten herbs which he thought "enough for the purpose of an ordinary physician." His classification is made on a pharmacological basis and to epitomize, there are quoted as emetics, salt, mustard seeds, and copper sulphate, as

purgatives, castor oil, as a stimulant, turpethum and sulphur and mercury preparations, and as an anthelmintic, embelia. Cannabis was recognized to be sedative and datura is inebrant but muscaria seems to have been recorded as narcotic. Cardamomus, chiretta and cane sugar have also been brought into use.<sup>12</sup> This rapid development of Hindu medicine is often regarded as a result of Grecian influence, but this is difficult to accept since most of the remedies are indigenous. It seems more likely that investigation of native herbs by the Brahmin was inspired by travellers from Egypt and Assria in a period (Aurvedya) anterior to Charaka.

About 1000 B.C. Egyptian and Mesopotamian therapy began to influence Greece, thus Homer tells of Helen receiving from the Egyptian Polydamna her knowledge of a soporific, which was probably opium to abolish grief and pain and he testifies to the superior skill of Egyptian physicians.<sup>13</sup> Homeric therapy shows little trace of theurgy but in the Asclepian temples drug therapy became subordinate to mysticism<sup>14</sup> and it was only when the Asclepiads divorced them from the priesthood at Cnidos and Cos that medicinal substances received appropriate homage again. The majority of the drugs in the Hippocratic collection are of Egyptian origin, and there are traces of resemblance in some prescriptions to those of the Ebers Papyrus, the few remedies of Indian origin were probably acquired through Phoenician traders.

I must not delay to eulogize Hippocrates; historical times have been reared with a substantial materia medica derived from ancient civilizations, the list was constantly being increased by addition of herbs collected by the physicians themselves or brought to them by the pharmacopoli, botanologoi and rhizotomoi. This knowledge was collated by Theophrastus in his *De Historia Plantarum*, a treatise describing some five hundred herbs. That the actions of these drugs were imperfectly understood needs no emphasis but attempts were made in the Alexandrian school by Hierophilus and Heracleides to determine their activities and regulate their mode of administration—for example those of opium as a soporific. In the same period the inebriate tenants of thrones instituted pharmacological experiments upon their subjects and to Mithridates VI, King of Pontus or his rhizotomist Krateras (120-65 B.C.) is due the universal antidote, emicridation and the conception that tolerance to poisons may be acquired. During this period the doctrine of the four humours developed and its extension to the four qualities of drug which did much to obscure their actions during the dark ages, the doctrine although ascribed to the Pythagoreans was there is little doubt founded on Egyptian religious tenet.

With Rome as the centre of culture there commenced a period of polypharmacy and uncritical empiricism when the rarity, secrecy or complexity of the compound was its chief claim to virtue, as in the famous theriacum of Andromacho—a panacea of some seventy ingredients—which remained in vogue till the *London Pharmacopoeia* of 1746. The Roman period however was not entirely decadent, and Dioscorides deserves recognition for his attempt to simplify therapeutics by his succinct descriptions of the remedies of his times.

I must leave the early results of empiricism with the statement that by making a rough classification of the present vegetable materia medica we can discover that 30 per cent of the crude drug are mentioned in the Ebers Papyrus, Assyrian tablets or early Brahminical treatises, that 37 per cent were known in classical times, and by including the drugs introduced by the Arabian school we reach 50 per cent of the whole. Among the remedies handed down from antiquity occur practically all the demulcents, flavour or carminatives, purgatives, and anthelmintics of but efficient occurs in Dioscoride and chiretta as a stimulant in Susruta, orange and lemon esopped Cero-Roman notice and were introduced by the Arabian. Of vegetable astringent, gall myrobala, and badru were used but astringent are also salts were preferred squill which was probably only an emetic with the Egyptians was a diuretic for drops in classical times. Opium was recognized as a soporific and hosecramus and datura as deliriant narcotics, knowledge

of the sedative properties of emmibus seems to have been transferred from India to the Arabians.

It may be said that, with the exception of the drugs introduced by the Arabian school—namely, rhubarb, senna, camphor, nutmegs, cloves, sandalwood, cassia, and turpentine, which probably emanated from India—the materia medica of Dioscorides was the foundation upon which medicinal treatment was based down to the advent of the renaissance in medicine, and that confusion of the pharmacological facts discovered by the ancients resulted from the doctrinal controversies concerning therapy which were waged down to within comparatively recent times.

The next important source of new remedies was the discovery of America, but the accounts of the introductions give us little concrete information as to the original reasons for their selection. Tobacco was discovered in Cuba in 1492, and guaiacum wood (*lignum vite*, *lignum sanctum*) reached Europe from San Domingo shortly afterwards. Friend states that Gersilvo Ferrand, in search of a cure for syphilis, found guaiacum used with success in the West Indies, and was the first to import it,<sup>15</sup> but Oviedo is also credited with its discovery in 1514.<sup>16</sup> Its fame as a tinctment for the "French Poxes" must have spread rapidly, because its virtues were extolled in 1519 by Ulrich von Hutten, whose work was published in English by Thomas Parnell in 1536,<sup>17</sup> and it was mentioned in conjunction with mercurialunctions and fumigations by Fracastoro in 1530.<sup>18</sup> It was Paracelsus, of course who popularized the employment of mercury internally in the disease.

A little later saissaparilla was introduced from New Spain and Honduras, and from about 1553 was recommended in the sudorific treatment of syphilis.<sup>19</sup> Jalap root was found in Mexico, and the Spanish physician Moanides refers to it in 1555 as the "rhubarb of the Indies"; the same author seems to have introduced the balsams of tolu and Peru.<sup>20</sup> The use of ipecacuanha for the "bloody flux" in Brazil is recorded in 1625 on the authority of a Portuguese friar,<sup>21</sup> but it was not until 1680 that Helictius, acting on information gleaned from

Paris merchant advertised its virtues in dysentery and, having successfully cured the Dauphin of France by its aid, sold his secret to Louis XIV for 1,000 louis d'or.

The mode of introduction of cinchona is almost mythological. Local legend suggested that the waters of a lake, into which cinchona trees had been overthrown by an earthquake, were found curative of ague, but it seems more probable that the value of the bark was known in Peru, and that a grateful servant imparted the knowledge in 1630 to the Governor of Lima, who transmitted it eight years later for the treatment of Countess Ana of Chinchon, wife of the Peruvian viceroy. Her cure led to its use a year later in Madrid under the name of "Countess's powder." By 1650 it had been widely distributed by the Jesuit priests, and acquired the name "Jesuits' powder." Thomas Willis mentions its value, and Sydenham in his *Methodus Curandi Febres* (1666) describes its use, but Sir Robert Talbot, an "irregular" practitioner, was mainly responsible for establishing its use by effecting with it the cures of Charles II of England and the Dauphin of France.<sup>2</sup>

The seventeenth century gave birth to physiology and histology, but the numerical and miscellaneous list of nearly 2,000 remedies which in 1618 constituted the first *London Pharmacopoeia* was an infant in which the sins of its fathers far more than the third or fourth generation were apparent even Culpeper, immortal quack, could make much at its expense.<sup>3</sup>

The eighteenth century has a more creditable record, the fourth and fifth *London Pharmacopoeias* were still idolized of skatological, astiological, and folk therapy, but the critical essay *Intithecologia*, by William Heberden (1745), was successful in banishing mithridate, theriac, and other superstitious nostrums from the sixth *Pharmacopoeia* of 1788, in which were approved the "diaphoretic powders" of Thomas Dover and of James, kino, which we owe to Fothergill, and senega, which, used by the Indians for rattlesnake bite, was advised by Dr Tennant, a Scotsman in Virginia, for pleurisy and pneumonia.

About this period Thomas Fowler, an apothecary of York, who had acquired in Edinburgh degree, analysed a patent medicine which was advertised as "tasteless igne and fever drops," and found it to contain arsenic. He devised the well known "Fowler's solution" (1786), and reported its effects in agues, remitting fevers, and periodic headaches, credit for the rational use of arsenic is thus due to a quick remedy.

Two triumphs resulting from the observation of folk medicine were the establishment of vaccination by Jenner in 1796 and the introduction of digitalis by Withering, an Edinburgh graduate, in 1785.<sup>22</sup> Bigot also was probably derived from folk medicine; it was known as an abortifacient during the sixteenth century, but did not come into general use as a uterine stimulant till the beginning of the nineteenth century.

The rapid advances in the nineteenth century were consequent on the development of chemistry with its discovery of the alkaloïds, and upon the knowledge gained through experiments upon animals. Magendie (1821) was a pioneer in determining the actions of bromides, strychnine, and morphine, and in showing their therapeutic applications. Magendie's mantle descended upon the Edinburgh school, and I need merely mention the names of Sir Robert Christison, David Wardle, Sir James Young Simpson, Alexander Cunn Brown, Sir T. Lauder Brunton, Sir Thomas Fraser, and Sir E. Sharpey-Schaefer to recall to mind the therapeutic advances for which experimental investigations were responsible. Another circle of experimental work was Dorpat, through which passed to larger spheres of influence Diengendorff, Buehheim, Schmeideberg, Robert and Hans Meyer.

The number of drugs introduced by modern experimental methods has been large, those which have survived the test of clinical experience are familiar to all, and I need do no more than remind you of some outstanding examples. Carbohe acid was introduced as an antiseptic by Lister in 1867, myl nitrite for angina pectoris by Brunton in 1867, chloral by Liebreich in 1869, cocaine as a local anesthetic by Koller, and antipyrine by Fehle in 1884, strophanthus by Fraser in 1891, and adrenaline by Sir J. Sharpey-Schaefer in 1894.

The late Sir Clifford Allbutt once said of Friend's *History* that "he spread his net too widely," the present endeavor to epitomize the evolution of remedies suffers from the exigencies of time and space, but its imperfect generalizations will, I trust induce some of my readers to elaborate and qualify the principles which in various periods have been involved in the introduction of new remedies.

## Memoranda: MEDICAL, SURGICAL, OBSTETRICAL.

### TRAUMATIC RUPTURE OF MALIGNANT OVARIAN CYST

THE recurrent traces of this case render it worthy of record.

A girl aged 17 in good health while at play with some of her fellow workers received a severe blow in the abdomen somebody jumping on to it. Shortly afterwards she was seized with severe diffuse abdominal pain.

On admission to hospital the temperature was 99.8, the pulse 102, and the respirations 23. The upper half of the abdomen was tender and the upper half of the right rectus rigid, no bruising of the abdominal wall was observed. The patient's condition improved soon after admission and it was decided to wait. Ten days later signs of free fluid in the abdomen were evident and operation was urged.

**Operation.**—The abdomen contained a large amount of clear pale fluid. A large polycystic papilliferous ovarian cyst on the left side had ruptured, the right ovary was small and there was a tear 2 inches long in a loop of small bowel which had penetrated down to the mucous coat. The rest of the abdominal organs were healthy. Both ovaries were removed, the tear in the bowel sutured and the abdomen drained. The patient made a good recovery.

The pathological report was to the effect that there was a columnar-celled carcinoma of the left ovary.

On examining the patient two months after discharge from hospital the whole of the left iliac fossa was found to be occupied by a hard painless mass.

The patient died at home seven months after the injury, no post-mortem examination was made.

My thanks are due to Dr J. F. Hodgson for permission to publish this case.

Northwood Middlesex.

H. JAMES MPCS

### CONGENITAL OCCLUSION OF THE SMALL INTESTINE

On June 26th a female infant, 36 hours old, was admitted to Dewbury Infirmary because it had not passed meconium since birth, nor had any come away when the child was being born. It was well nourished, weighed 8 lb 2 oz, and was normal in every way except for slight distension of the abdomen. A thick plug of mucus was passed after a rectal examination, which discovered nothing abnormal.

The infant vomited on an average three times a day but refused to eat any part of a feed of food appropriate and natural to the child. No movement of the bowel occurred. The superficial veins of the abdominal wall became enlarged and visible as longitudinal channels with tortuous communicating branches. The abdomen became enlarged and on July 1st the child, which had gradually become emaciated, looked not extremely ill.

On post-mortem examination it was found that the stomach and the posterior half of the small intestine were considerably enlarged, the small intestine appearing as large as the middle and terminating abruptly in a bulbous end. From the remainder of the small intestine was continued a small tube about the size of a goose-quill and ending in a vermiform appendix and the whole of the large intestine was present in perfect maturity. The portion of the intestine below the dilatation had a complete lumen which contained nothing of the nature of meconium. The contents of the upper portion were fluid and yellow. Between the dilated and undilated portions of the small intestine there was a complete partition of mucous membrane which exhibited only a simple opening at the point where the vermiform should have been unbroken. The point of occlusion was well below the point of entry of the ileal duct and its existence was explained as being due to proliferation of the epithelium in the second month of foetal life.

Gen. & Infirmary, Dewbury.

BERNARD SHEA M.B. B.Ch.

### A CASE OF SCLERODERMA

Cases of scleroderma are of sufficient rarity to warrant a short description of a case I had under my care for several years.

The patient was a girl apparently normal in external make-up and physically until she reached the age of 13. It was then noticed that a few hours in the night her face was becoming white and that below the brow was a patch of skin about the size of a penny which the mother described as a "pale" colour. There was no disturbance in her general health. The patch gradually extended and fresh patches appeared on the right side of the neck extending as far back as the nape and a line ran from the shoulder down the inner side of the arm and for arm. The eyebrows and eyelids became involved on the affected side. A few weeks later the hand, forearm, and wrist showed signs of brown pigmentation and a little later the right side of the back commenced to discolor. A patch on

two well defined bands running forward one to the lower end of the sternum and the other just above the umbilicus, leaving the same distribution as the usual herpes. A very definite line appeared from the right anterior superior spine to the inner side of the knee and a right diffuse patch on the anterior surface of the leg and foot.

The whole process gradually developed. The hand soon discolored eventually becoming deeply pigmented (see photograph of face). The area of hair affected extended to the right axillary hair, became white as also did the right half of the pubic hair. The bones on the whole of the right side of the body, including skull, jaw bones, and clavicle ceased to grow excepting the arm which I think grew an inch in length after the onset. The hand became markedly impaired particularly the leg.

About six months from the onset deep ulceration occurred on the anterior surface of the leg. It continued for eighteen months and at the end the limb was completely withered and the muscle bone skin and tissue seemed glued together and atrophied. During this time the pigmented skin had become hard and non-elastic. The mouth had become drawn by the contraction of the skin and the ear had partially undergone a similar movement. The gums and lip on the right side atrophied and the teeth on this side were exposed almost in their entirety. The tongue was smaller on the affected side and the right nostril became more or less obliterated. Salvation became very troublesome and the right corner of the mouth eventually developed into an ulcerated mass. To add to her burden she became completely deaf in the right ear and almost blind in the right eye. The use of the arm improved a little at the end of a year. It never became ulcerated or ankylosed as did the leg and she was able with difficulty to do knitting and a crochet work.

She lived for ten years after the onset. The left side of the body grew normally. She was not affected mentally at any time. She eventually developed tuberculosis in the right lung and died from a profuse haemoptysis.

She had not had any previous illness and the family history revealed nothing abnormal. The other eight children are well and alive to-day as also are the father and mother.

### PITYRIASIS ROSEA: A SECOND ATTACK

It is exceedingly rare to meet with a second attack of pityriasis rosea, Graham Little described one in 1915. Owing to this rarity as well as the strong suggestion of direct inoculation which occurs in the following case it may be thought worthy of record.

#### CASE I

In August 1923 a mother brought her child, aged 10, as he feared the girl had ringworm. The body she had noticed a red ring on the child's right arm, the day before and I found midway between the costal border and the crest of the iliac an oval slightly raised patch pink and early at the margin, dilated yellow at the centre. The child said that the place itched slightly. The lesion had none of the characteristics of ringworm and the fungus was discovered by the microscope. There was no question of eczema, scabiosis, could be excluded. Pityriasis capitis was not present and there was no doubt that the patch was the herald of pityriasis rosea. In the course of two or three days the first crop of lesions appeared and by the end of a week the eruption had developed in the typical eruptive area of pityriasis rosea. In order of baths of Condy's fluid and a saline acetic ointment (2 p.c.). In ten days the child was free of the disease. The eruption had covered more of the body than of the first crop. The spots crossed by a fine line though both types of lesions were present. There was no fever and no glandular enlargement. The stomach was normal in its

#### CASE II

**First Attack.**—Fourteen days after I saw the patient for the first time I discovered on her own person midway between the umbilicus and the xiphisternal angle a reddish-yellow slightly irritable patch which rapidly developed into a typical herald patch. In the following seven days successive crops of small patches appeared most of them becoming medallion with central clearing and a pink and a cream margin. The eruption occupied exactly the herald patch area and included the upper part of the thigh. There was slight itching. No fever and no glandular enlargement were present. I used baths of Condy's fluid daily and mercuric iodine ointment in three weeks.

**Second Attack.**—Ten years later in June 1927 I discovered the patient on the same place a lesion. It rapidly developed into the typical herald patch and in the course of seven days the eruption was complete occupying exactly the herald patch area. In contrast to the previous attack more of the lesions were medallion. A certain number of these smaller

lesions had mitral characteristics. There was again slight irritation, but no fever or glandular enlargement.

On this occasion I employed no treatment at all, being curious to know how long the disease would last. I was clear of lesions in eight weeks.

The cause of this obscure and comparatively rare disease is unknown. A curious fact, however, demands mention. In examining the child whose case I have described, I gently scratched the lesion on her body with the nail of my right forefinger, and immediately afterwards, feeling the effects of the industry of *pulex irritans* (donation of a previous patient), I involuntarily applied this finger to the spot where I felt the irritation—that is, midway between the umbilicus and the xiphisternal angle, and slightly scratched the place. This was the area where I subsequently found the primary lesion of pityriasis rosea in myself. It might, of course, have been mere coincidence, but if the disease be of microbial origin it is at least conceivable that I inoculated myself, by scratching, with the causative agent.

Vidal in 1882 described the *Microsporon ananassae*, which he believed to be the cause. Du Bois has found a cryptogamic organism with small spores in the glandular orifices and follicles. Neither of these organisms has been shown to be the cause.

Although there is no certain evidence of contagion in pityriasis rosea, yet the primary condition, succeeded by an eruption of secondary lesions, suggests the possibility of microbial origin. I think the history of my first attack significant, though I cannot account for my second. I had not seen a case of the disease in the interval between the two attacks, though it is of course possible that I may have been in contact with a case in a public conveyance or place, or I may have examined a patient in whom the disease was going to occur. It is curious that the disease should be so strictly confined to the rest area.

#### CLOSURE OF ABDOMINAL INCISIONS

The publication of Mr. Strong Hemeny's note on the closure of abdominal incisions, on June 25th (p. 1143) induces me to send the following account of a method I have often used.

Three strips of good antiseptic adhesive plaster, 14 to 16 inches long and 2 inches wide, are cut as shown in the diagram, each bridge being 2 inches long. After placing a moderately hot pad

over the abdominal surface for a minute, the skin is dried, the plaster applied first on one side, far enough to allow the bridges to rest over the wound. The assistant, grasping the abdominal wall, brings the edges of the incision into apposition, then the other end of the plaster, tightly drawn, is applied to the opposite side. With the three strips thus applied the edges of the wound are held tightly together. A little bismuth-iodine-iodide is then dusted over the wound and the dressings applied. If necessary, they can be removed duly, and the condition of the wound observed. I have found that the plasters hold firmly even in cases of severe vomiting after the operation. This method could be applied to any part of the body, or face and extremities, where the surface is suitable, thus rendering it unnecessary to stitch a face wound in particular. The size of the strips depends on the size and locality of the wound, thus, on the face, I use strips 3 inches long and 1 inch wide, with only one bridge in the centre. By this method, if on duly examination the wound does not look too healthy, hot antiseptic pads might be applied.

#### CONGENITAL TUMOUR OF THE BREAST

CONGENITAL tumours of the breast are sufficiently rare to make the following case worthy of publication.

On November 17th 1926 I saw a male Hindu infant fourth in the family, aged 3 days. The birth had been attended by a trained midwife under the supervision of the health visitor, and was reported as normal. There was a well defined swelling about the size of an orange on the outer side of the right nipple, which pushed the arm away from the side. The swelling was cystic,

not adherent to skin or muscle, and appeared to have no connexion with intrathoracic contents. No secretion was obtained from the nipple, and no enlarged glands could be felt.

The infant was breast fed and seemed to suffer no inconvenience apart from the pushing of the right arm away from the side. No treatment was undertaken, but the infant was seen weekly. It was proposed to operate at once if the swelling increased in size. I first saw the infant on March 2nd 1927 when the swelling had decreased to the size of a walnut. The family then moved to their village, and the further progress of the swelling cannot be watched.

I am indebted to the civil surgeon, Colonel T. Hunter, for advice and for seeing the case from time to time.

## Reviews.

### THE PATHOLOGY OF THE PITUITARY GLAND

It was in the year 1886 that Marie introduced us to the disease which he named acromegaly, and which on the anatomical side is characterized most obviously by the enlargement of certain structures of the body, among them the pituitary gland, at that time regarded as a structure of no importance. This was the starting point of a series of observations which form one of the most fascinating chapters in medical science. In the forty years that have since elapsed we have learnt that the pituitary gland is one of the most important organs in the body, some half-dozen different diseases or syndromes have been defined as dependent on its dysfunctioning, the effects of a deficiency in its secretion have been demonstrated experimentally, and the experimental induction of a condition analogous to hypersecretion has recently been successfully accomplished by Evans of the University of California, and Tracy Putnam in Cushing's laboratory. The time is, therefore, favourable for taking stock of our position as touching our views on the nature of acromegaly and of the possible directions in which further advance is to be looked for, a subject which has been expounded with great clarity and personal charm by HARVEY CUSHING in his oration before the Medical Society, published in the first two numbers of this volume of the *BARRISTERS MEDICAL JOURNAL*, and with some additional details in his monograph on acromegaly, written in collaboration with Ivo Davidoff and published by the Rockefeller Institute for Medical Research.

When the functional importance of the pituitary gland came to be recognized it was natural that a causal connexion between the gland and acromegaly should be suspected, and it was thought, somewhat illogically it would seem, that the constantly observed enlargement of the organ indicated a diminution of its secretory activity. Experimental removal of the gland, however, proved that this was not the case, and that a diminution of function caused by pituitary removal was followed by effects that were just the reverse of acromegaly. Opinion then veered round in the direction of hyperpituitarism, and this view held its ground in spite of certain difficulties which presented themselves and seemed to militate against it. There were cases in which the lesion seemed to be in questionably destructive in its effects, actual neoplasms for example, while from time to time the *post-mortem* examination revealed no enlargement of the pituitary gland at all. The slight logical uneasiness incident to the latter fact was, of course, readily allayed by the consideration that a gland might be secreting in excess, although not enlarged. These difficulties have, it seems, been definitely removed by a notable discovery made by Benda in 1900. He has shown that the cells of the pituitary enlargements in acromegaly always contain acidophilic cells (cells containing granules stainable with acid dyes such as eosin) similar to those present in the normal gland, and that this is the case even where the lesion was regarded as an actual neoplasm. In other words the

<sup>1</sup> The Pathological Findings in Four Autopsied Cases of Acromegaly with a Discussion of their Significance. By Harvey Cushing, and Ivo Davidoff. Monographs of the Rockefeller Institute for Medical Research No. 22. New York 1927. (Sup. roy. 8s. 6d., pp. 131, 104 figures, 2 de ara.)

apparent neoplasms were shown to be in reality hypertrophic. As with thyroid enlargements there is room for discussion of the best designation for such tumours, whether hyperplasia, nodular hypertrophy, or adenomatous hypertrophy, the point of importance is that the constant presence of acidophile cells in all enlargements which are associated with acromegaly may reasonably be held to indicate an active secretion. With regard to those cases where no enlargement of the gland is present it has been shown in one or two instances that the number of acidophile cells is increased, and it remains to be ascertained whether this is so in all.

There cannot now be any reasonable doubt that acromegaly is caused by overfunctioning of the pituitary gland though we have no evidence as to what brings this about. Further progress in the immediate future is indicated rather in the direction of defining the complete syndrome in acromegaly, attention in the past having been riveted somewhat exclusively on the skeletal and pituitary changes. Cushing and Davidoff have taken up this line in their monograph, with a view to rounding off the clinical picture of the disease. They have made a thorough anatomical examination of the tissues and organs in four cases differing considerably in their clinical course and manifestations and by a comparison of results have ascertained what changes are common to all four and are therefore probably directly due to the pituitary lesion and not to some secondary influence. The constant findings in these cases were (1) the commonly recognized overgrowth of the mesodermal tissues, (2) the less commonly emphasized and disproportionate enlargement of the viscera especially the liver and kidneys, (3) more or less general polyglandular anomalies accompanied by a tendency to the formation of adenomata, and (4) a hyperplasia or adenoma of the pituitary gland. With regard to the polyglandular changes some of the organs—the sexual glands for example—tend to become atrophic others like the pineal gland appear to become functionally inactive or at least counteracted in their normal activity, while still others—the thyroid parathyroids, thymus and adrenal cortex—are not only enlarged but appear to be functionally activated. Moreover the tendency of the end glands to become adenomatous like the pituitary gland itself is so marked that it would seem almost justifiable to speak of acromegaly as a disease characterized by a pluriglandular tendency to adenomatous formations.

It would not be unreasonable to suggest that these polyglandular changes may be due to one common cause acting on the glands independently and not indirectly through the pituitary gland. Against this there is the fact that extracts of the pituitary gland are capable of producing in an experimental animal overgrowth not only of the mesoblastic tissues but enlargement of the viscera as well, together with changes in the ductless glands comparable to what is seen in acromegaly.

### CYSTOSCOPY

Few foreign works on cystoscopy have appeared but few in the English language. Mr J. B. MACALPINE'S *Cystoscopy* has therefore, few British competitors. It is more than an atlas of cystoscopy, it is a theoretical and practical handbook that contains in addition chapters on renal function and pyelography. The preparation of the book has entailed a great deal of work, notably frequent journeying by Mr W. Thornton Shiells the well known medical draughtsman, from London to Manchester in order to prepare the excellent cystoscopic paintings with which the volume has been generously illustrated. The opening chapters deal with the history of cystoscopy, the structure and optics of the modern cystoscope, and the technique of cystoscopy. In his preface the author acknowledges his debt to Mr Schranz of the Cento-Urinary Manufacturing Company, for help in dealing with the optics of cystoscopy, this difficult subject has been exceedingly well handled, just sufficient details being given to enable the reader to appreciate the construction of the cystoscope without being

overwhelmed with unnecessary technical points. Mr Macalpine does not apparently consider it necessary for the cystoscopist to be in possession of a large number of different types of instruments, for he describes only the ordinary cystoscopes in general use. As however, the work is primarily intended for surgeons whose opportunities for using the cystoscope are not sufficiently frequent to make them skilled in its employment the decision to avoid describing instruments not in general use is perhaps a wise one. Nevertheless it is an incontestable fact that certain regions of the bladder and not only its neck are more easily investigated by such instruments as Woolf's cysto-urethroscope than by the ordinary cystoscope. After describing the appearance of the normal bladder and the variations of the ureteric orifice which are commonly met with the author deals with pathological conditions. There is a description of the inflammatory conditions of the bladder and of the changes in the mucosa associated with this condition. Another chapter is devoted to a consideration of tuberculosis of the urinary tract, it deals with the diagnosis of the disease the means by which a decision is reached as to the site of primary lesions and methods of investigating the function of the unaffected kidney. Neoplasms of the bladder are described and their treatment by per urethral methods is discussed. Considerable advances have recently been made in cystoscopic methods of treatment and it is perhaps a pity that the author has not mentioned some of the new models of cystoscope that have been introduced for the specific purpose of treating bladder growths. To deal with a large growth by means of diathermy applied through an ordinary catheterizing cystoscope is very difficult especially if bleeding is occurring at the time of operation. In these cases such instruments as Woolf's irrigating cysto-urethroscope and Kidd's diathermy cystoscope are invaluable. Indeed their use may be a vital necessity and for lack of them it may be necessary to employ open methods. The omission of any mention of these instruments from Mr Macalpine's description of diathermy of bladder growths is rendered more striking by the fact that in the following chapter dealing with vesical calculi he gives a description and illustrations of a cystoscopic lithotrite, an instrument few general surgeons possess. In an excellent chapter on stones in the ureter the author describes the use of the wax-tipped bougie, Buerger's dilating olives and scissors and Bransford Lewis' ureteral dilator. The book concludes with a long chapter on pyelography well illustrated by plates.

It is impossible to read Mr Macalpine's treatise on cystoscopy without being impressed with the amount of labour expended on it both by the author and by the draughtsman associated with him. In a book devoted to cystoscopy the quality of the illustrations and coloured plates is of paramount importance and the fact that Mr Thornton Shiells has been responsible for these is a guarantee of their excellence. Fortunately little has been lost in the process of reproduction and author, artist and publisher are all to be congratulated on the result. The surgeon who employs that important therapeutic weapon—the cystoscope—only occasionally and even those who are more expert in its use will find here much that is helpful.

### ANATOMY OF THE CENTRAL NERVOUS SYSTEM

PROFESSOR GEORGES GUILLAIN and Dr IAN BEATTIE have produced a notable volume in their *Anatomie Topographique du Système Nerveux Central*. Working together in the laboratory of the Salpêtrière they aimed at producing a book which should be of moderate size but of a wider range than the schematic textbook suitable for students. For this reason schemata or diagrams are avoided altogether and the sixty fine plates which illustrate the work are all photographic reproductions of macroscopic and microscopic sections of the several parts of the central nervous system. The illustrations have been chosen with great care and with a view to rigorous

*Cystoscopy*. By James T. Macalpine, F.R.C.S. (Ed.), F.R.S. (Wimp.) and Son, Ltd. London: Simpkin, Marshall, Hamilton, Ker and Co. Ltd. 1927. (Med. Div. pp. xvi + 22. 161 figures, 12 plates, 2s. net.)

*Anatomie Topographique du Système Nerveux Central*. By Georges Guillaumin and Ian Beattie. Paris: Masson et Cie. 1926. (Imp. Bro. pp. vii + 22. 60 p. c. Pp. x cover. Ed. fr. board 50 fr.)

anatomical exactitude, they form the basis of the work. The text consists of descriptions of the naked-eye and histological anatomy as revealed by the plates, and physiological and clinical considerations have been omitted as the work is intended to be purely anatomical. It will prove of great value to house-physicians and others working systematically in the wards and laboratories of neurological hospitals, and for such it was primarily written, but the general physician also will find it a book which he will be glad to possess for reference as an authoritative guide in the elucidation of clinical cases and *post-mortem* appearances. Accurate anatomical knowledge is at the basis of neurological diagnosis and must precede physiological and clinical deductions in a sound neurological training.

The publishers have maintained their high reputation in the production of the plates, the printing of the text, and the binding, and the price for a volume of such a high standard is not unreasonable.

Messrs Masson, publishers of so many classical French neurological works, have added to their series an admirable small volume on the *Neurologie Elementaire des Centres Nerveux et du Sympathique chez l'Homme*,<sup>1</sup> by Professor P. GILIS of Montpellier. It is a straightforward account of the essential facts, and will be found of convenient size for the student and useful also in post-graduate classes, and for revision by physicians and teachers. A short account of the development of the nervous system is followed by a systematic description of the sensory and motor centres and tracts. The spino-thalamic tract is described after van Gehuchten as passing through the cerebellum, not directly through the brain stem to the thalamus. It is curious that the author should maintain this view, although it is abandoned in the second edition of the late Professor van Gehuchten's textbook. The account of the extrapyramidal nuclei and tracts is up to date and some guided clinical deductions are made. A very full account, occupying half the book, is given of the autonomic nervous system. The author is anxious to emphasize the anatomical unity of the cerebro-spinal and autonomic nervous systems and, as far as possible, the description of both follows identical general lines. There are some excellent diagrams and one plate.

### MALARIA ITS INVESTIGATION AND CONTROL

The object of this book on *Malaria*, by Major ROBERT KNOWLES, I.M.S., Professor of Protozoology in the Calcutta School of Tropical Medicine, and Mr RONALD SENIOR-WHITE, malarial research officer to the Central Malaria Bureau, India, is explained in the preface as follows: "Numerous as are the existing books on malaria, there at present exists in India no suitable handbook which can be put into the hands of medical men of the assistant surgeon class to help them in their malarial problems." It may with confidence be said, however, that this monograph will be welcomed by a much larger audience. The chapters on the life cycles of the malarial parasites, the laboratory diagnosis, and treatment of malaria are by Major Knowles, while Mr Senior-White is responsible for the chapters on malarial survey work and antimosquito measures.

The book is eminently readable and practical, and well illustrated, and the results of recent researches on malaria have found a place. All statements are submitted to a running commentary which assists the reader in assessing values and in noting the paths along which further investigations may go. It is impossible to deal at length with the several sections of this monograph, but it may be mentioned that the Sinton alkali-quinine method of treatment is advocated, and the general use of intramuscular injections of quinine condemned in no uncertain terms.

The later chapters on antimalarial work are full of practical points and important details, and upon such

matters success depends. There are appendices on breeding places and distribution, specifications for engineering work, and keys to mophelines, both adult and larvæ in the Indian subregion.

### BINOCULAR VISION

There are few who realize what an important part the faculty of binocular vision takes in work and in play. Those who do not possess the faculty may not consciously miss the possession, but they are aware of an incapacity to compete with their normal fellows in certain games and in forms of work. In no calling is the possession of this faculty of more importance than in flying. It has been ascertained that the chief risk of flying is landing, and that it is gravely accentuated when there is any defect of this faculty of binocular vision. The work of Flight Commander Clements and of some of the American Air Force surgeons has proved conclusively that the risks are inversely proportional to the degree of binocular vision. When it is highly developed judgement of distance and position is at its best and landings are well made, when it is poor, either by reason of congenital pooriness or disturbed because of illness or fatigue, then judgement is weak and landings are apt to be crashes. There is no absolute standard for this faculty any more than there is for that of visual acuity. We arrive at an average standard and check each man's capabilities against that. By such tests it is possible to grade the liability to risks amongst flying men. Clements used Humm's diaphragm test largely with that instrument it was possible to make the eyes walk, as it were, on a tight rope or if they failed at that to provide a plank, or a pavement, or a hole, breadth of street for their balancing, and the control of eyes in these several conditions is as variable as bodily stability in these actual standings. Dr KENNETH R. SMITH has been in the service of the Royal Air Force, and is therefore familiar with these facts. He has written an attractive little pamphlet<sup>2</sup> emphasizing these points, and believes that much may be done to remedy defects by definite exercises. He uses an instrument which is essentially Javal's binocular test. To a baseboard is fixed at one end a desk for printed matter or the like the other end the observer places against the face, at a certain distance before the nose there is an extended post, which obscures for one or other eye corresponding parts of the print which are seen by the other eye where there is binocular vision. All these devices are useful as tests, and some of them are invaluable in showing patients where they fail. But we have some doubt whether practice with such instruments for a few minutes or even up to an hour a day (and they are too monotonous for longer periods) will alter an inborn incapacity which is dominant for all the rest of the day. We should have thought that any development that was possible would be best attained by assiduous practice at games such as lawn tennis, there is no doubt that high skill in this game only comes to those with perfect binocular vision, where hand and eyes are in such intimate and automatic association that the judgement is perfect. Golf for this purpose is useless, a one-eyed man can do most of the shots just as well as he who has the best binocular vision, perhaps better. Dr Smith's little book is of interest and worth reading.

### PRINCIPLES OF THE HUMAN ECONOMY

We have read a good many primers on human nature and physiology designed for different sections of the public, from school children to wives and mothers, but for the most part these have not greatly attracted us, either on account of their failure to convey instruction with few words or because they did not succeed in conveying to the mind something more than a mere catalogue of facts. But there is a book before us—*The Human Body*, written by Dr TREVOR HEATON, Dr LEES PRADDER

<sup>1</sup> *Anatomie Elementaire des Centres Nerveux et du Sympathique chez l'Homme*. By P. Gilis. Paris, Masson et Cie, 1927. (5½ x 8 in.) 232 p. 25 diagrams. 2 plates. 20 fr. (any majoration).  
<sup>2</sup> *Malaria: Its Investigation and Control*. By Robert Knowles, Major I.M.S., and Ronald Senior-White. Calcutta, Thacker, Spink and Co. 1927. (7 x 10 in.) pp. vi + 263. 29 figures. 6 plates. Rs. 7/8.

*Some Facts about Binocular Vision*. By Kenneth R. Smith, M.D., late R.A.F. Service. Dimpbley and Sons, 14 King's Street, London, S.W. 1. 1927. (Pp. 20.)  
*The Human Body*. By Trevor Heaton, M.D., and Lees Pradder. Series. London, Chatto and Windus, 1927. (5½ x 8 in.) pp. 160. 7 plates. 7/6 net.

in Anatomy in the University of Oxford—which does attract us just because it is neither a catalogue of facts of elementary physiology and anatomy nor a bald narrative with no sense of the mystery of the human body within it. He has contrived to write one of the most fascinating books for the general reader that we have come across.

Dr Heston shows his purpose to be not so much to impart instruction as to awaken interest in a subject the approach to which is usually guarded by a ring-fence of technicalities. He intends his book to be readable and to provide some slight commentary on a number of matters of health and disease which do not as a rule pass the limits of knowledge of Vicarular's schoolboy. Of his success there is no manner of doubt: his book is readable for it is full of stimulating interest, not least commendable is the manner in which he has dealt with reproduction. For the most part books of this class leave the subject severely alone, either the authors dare not or they cannot write on the mystery of life. But here in three chapters on the internal secretions, reproduction and development and disease and death, there is a fine piece of writing that at once raises the whole tone of the matter to a high level of dignity and impressiveness. Facts are there, but the facts are so related to their purpose that mere curiosity is swamped by marvel, and the general reader who turns these pages will certainly be the better for their perusal.

### NOTES ON BOOKS

*Infernal Conduct* by MEDICUS is a tragic story of a well-meaning able but highly strung medical man who settles down to build up a practice and has a hard time at the hands of the medical men in the district who resent his intrusion as a plagiarist. A footnote explains that a plagiarist is a doctor who is up to a plate without first having a practice from an already established practitioner. Also every kind of minor misfortune happens to this unlucky man who, being in financial straits, becomes medical adviser to a new medical club for imitated persons, wins the secretary and committee of the club, is admitted to him canvas and idly in the paper, but he does not take the significance of this until he is summoned before the General Medical Council to meet a charge of infamous conduct in a professional respect, which obliges him that he commits suicide by taking prussic acid. The author hopes that the book will bring about revision of the terms of censure passed by the General Medical Council upon unfortunate transgressors. It has come to our notice that the publishers in their natural desire to push the sale of this novel have sent postcards to members of the medical press, on bearing the ambiguous legend "Infamous Conduct by MEDICUS. This book has been published at 6s. is of special interest to you. You should order it to-day. Though of course there cannot have been any intention to connect infamous conduct with the recipient it was surely ill-advised to send an advertisement so worded on a postcard especially to a country village where gossip is always rife.

The little book entitled *Management and Administration of Diet in Lunacy* has been revised and brought up to date. The matters dealt with are now arranged alphabetically, a change which will greatly facilitate reference. Since the first edition was published the Trustee Act 1925, the Settled Lands Act 1925, the Administration of Estates Acts 1925, and the Law of Property Act 1925 have all been passed, and additions and modifications consequent upon these Acts have been incorporated. Of medical interest are the affidavits which must be made by a medical attendant or medical superintendent of an institution when application is made for the appointment of a receiver. The book is concisely written and will be of value to those who are engaged in this special work.

A second edition\* of Dr R. FRANK'S handbook of recent pharmacological, physical, and dietetic treatment has been called for within a year, and this may have encouraged the publisher to send us a copy for review. The first part consists of a

brief description in alphabetical order of drugs and proprietary preparations, followed by lists of mineral water, prescriptive, tuberculous, serum, and antidotes for poison, as well as patent foods and other proprietary preparations, the ingredients of which are stated. The second part is devoted to the treatment of medical disorders arranged according to the various systems.

### PREPARATIONS AND APPLIANCES

*Modified Bozmann Uterine Curet*

Mr J. LYLE CAMERON, F.R.C.S. (London), has devised a modified form of Bozmann's uterine curet, which he states is a very convenient instrument for packing or for making applications to the uterus, cervix or vagina, or for introducing a drainage tube.

The improved forceps has the usual double curve and single catch rack, but the blades are rounded at the tip, longer and slightly tapering from the joint and cross-hatched inside for one inch from the tip. The handle is longer, the entire instrument is stouter and stronger in construction and since

it is made of stainless steel it is easy to clean and sterilize and very durable. The rounded end, which is the size of a No. 5 uterine dilator, greatly minimizes risk of perforating the uterus or vagina. The taper admits of its use to some extent as a dilator. Its cross serrations provide a ready grip for introducing or removing packing or drainage tubing or for holding a pledget of wool when making an application. The greater length facilitates packing a large uterus and allows the hand to be kept on the way. The outline of the forceps permits twisting when swabbing, painting or cleaning the cervix.

Mr Cameron adds that to the general practitioner as well as to the gynaecologist this should be a useful instrument—in conjunction with a Sims or Sims or Sims speculum, a vulsellum, a gauze roll or ribbon impregnated or not as required—when haemorrhage calls for quick and firm packing, also for painting or packing the uterus after curetting.

### THE AMERICAN MEDICAL HISTORY OF THE WAR

The volumes in which the Medical Department of the United States Army is recording its activities during the war are planned on a very large scale. We have already given an account of some of them. They are not being published in numerical order. We received a few months ago the sixth and the fourteen, the eleventh which came to hand in August will be noticed later. It is the first part of the section on surgery and includes general and orthopaedic surgery and the surgery of the nervous system.

The sixth volume has the title *Sanitation*. It is of the same bulky character as the volumes previously published, and is in two parts, each occupying half of the volume. Part I, compiled by Colonel W. P. Chamberlain of the medical corps, contains an account of the sanitary and hygienic aspects of recruiting, camp, barracks, organization and administration of the military forces of the United States previous to their embarkation for service overseas. Part II, by Lieutenant-Colonel F. W. Weed, deals almost exclusively with sanitary work in connexion with the American Expeditionary Force in France. We are warned in the introduction not to confuse the expression *sanitary* as used in the American Army with *sanitation*. The former term is employed in the continental sense, and must be interpreted to mean the army medical service generally. For example, the sanitary train of a division is the term used for the divisional group of field ambulance companies and field hospitals and the sanitary corps is the corps of enlisted men for medical services corresponding to our R.A.M.C. Sanitation in its restricted sense was administered from the surgeon-general's office.

The Medical History of the United States Army in the World War. Volume VI. Sanitation. Washington: Government Printing Office, 1926. (Sup. 110, 80 pp. 111, 100 pp. 10 charts and 5 figures in Part I and 55 charts and 12 figures in Part II. 35s. (dollar). Vol. VI. Medical Aspects of Gas Warfare. (pp. 270, 37 charts, 10 plates, 2-2 figures. 3 dollars.)

\* I am indebted to Mr. J. P. Mott for the loan of the book. (See also p. 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

in Washington by a sanitary inspection section, with a small body of itinerant sanitary inspectors numbering from four to eight.

#### RECRUITING

The opening chapters of Part I contain much that is of value as a guide to officers whose duties involve the sanitary inspection of camps, units, barracks, hospitals and other military institutions and consist mainly of copies of forms for inspection reports, together with selected examples of some of the reports actually submitted. The forms are of a very exhaustive character, and there must have been a vast accumulation of such reports in the surgeon-general's office. How far the recommendations of the inspectors were or could be carried out is another matter, for it would appear that the frequency of inspection was never up to the desired standard owing to the difficulty of obtaining a sufficient number of experienced and otherwise qualified officers for inspection services. The remaining chapters of this part of the volume deal with the usual subjects of military sanitation in the home territory, and with the physical examination of men on enlistment and on demobilization. All these subjects are treated in the detailed and documented manner which is characteristic of the United States medical history of the war, but is somewhat tiresome for general reading. Copies of forms, official memoranda, correspondence and so on, occupy a considerable portion of each chapter, and are, of course, of value historically and for educational and administrative purposes, but scarcely appeal to readers outside the United States medical service. It may be of interest, however, to note that the minimum physical standards for enlistment for men 21 years of age and upwards were 64 inches in height, 30 inches with 2 inches mobility chest measurement, 128 lb in weight, and 20/40 vision in right eye and 20/100 in left. These standards after June 5th, 1918, were lowered to 60 inches height, 110 lb weight, with auditory acuity from 20/20 in each ear to 10/20. The dental requirements, which at first were four serviceable opposing bicuspids or molars were increased to six, and six incisors or cuspids (canines) were also necessary. Recruits were classified in four groups, group A being men fit for general service, group B men fit after a remediable operation, group C men fit for special or limited service in a definite occupation, and group D men unfit for any service. Many difficulties arose with those men of group B who refused to undergo a remediable operation, as well as with those awaiting operation. Great numbers of the latter filled camps, barracks, and hospitals, occupying accommodation urgently required for group A men. The policy of having a deferred remediable class of recruit was consequently vexatious and a source of much trouble and controversy. It was eventually abandoned, and remediable cases remained in the army without operation or were discharged. The statistics of demobilization medical examinations are also interesting, although they are somewhat involved and incomplete. Four million are said to have been examined on demobilization. During the period November 11th, 1918, to December 31st, 1919, of these the number medically examined and the results reported was 3,133,921. As many as 2,936,780 were shown as discharged without any disability. The magnitude of the work undertaken by the American medical boards in this connection is worthy of notice.

#### PREVENTION OF DISEASE

The second part of the volume, dealing with sanitation in the American Expeditionary Force in France, is of the same detailed character. Only two diseases—epidemic diarrhoea and epidemic influenza—are stated to have developed sufficiently to cause excessive sick rates. Details are given of the organization for the prevention of communicable disease, such as delousing measures, disinfection of clothing, and destruction of rats. The measures employed were, as a rule, similar to those in force with the British armies. The same remark applies to the various measures of sanitation in connexion with purification of water supplies, disposal of waste products, shelters for troops, and so on. The well-known decontaminating plant assigned for use with the British troops was apparently copied by the Americans, although there is no

acknowledgement of the great value our experience and sanitary methods were to their troops and medical services in France. They coined a name, "sterilab," to designate this plant. It reminds us of the habit of the Japanese to concoct a new Chinese ideograph to designate a new invention. Details are given of the clothing and equipment of the U.S. infantry soldier, and of his rations. A weight of 50 lb is regarded as the maximum that should be carried by a man weighing 144 lb. The U.S.A. soldier's equipment and arms varied from 61 lb to 73 lb, with an additional 18 lb for clothing worn on the person. The Americans, however, were not called upon to make long marches, and there is no record of breakdown from carrying these excessive weights. The field ration was of high caloric value. At first it had a value of 4,871 calories, but this was reduced to 4,258 in 1918. Even then it was considerably higher than the allied and enemy field rations.

An interesting account is given of a mobile laundry, which was designed in the United States and shipped to France. The illustrations and details of this important unit are worthy of study. It is a new form of unit, the need of which was much felt by our armies in the field. Only four were shipped between June 5th and October 15th, 1918, but large numbers were ready for shipment by the time of the armistice.

One of the fullest chapters in the volume, a chapter of some hundred pages, deals with the prevention of venereal diseases amongst the American troops in France. A graphic description is given of the state of affairs. St. Nazaire, the chief port of disembarkation, where the American authorities came into conflict with the French over the question of putting licensed brothels out of business. The French authorities feared that the effect of the measure would be to increase clandestine prostitution and disseminate disease amongst the French women. As it had come to notice that a considerable percentage of the American troops on disembarkation were found to be suffering from syphilis or other venereal disease. Full details are given of the correspondence that took place on this subject. Among other suggestions by the French authorities was that at least three licensed houses should be open for American coloured men or that coloured women should be sent over for them from America, and that, failing acceptance of these suggestions, all coloured men should be sent back to the United States. None of these suggestions were accepted, and reliance was placed on the well-known prophylactic centres that were established by the Americans in France.

The size of the volume and the mass of information it contains do not permit of any extensive culling of other interesting points and we can only express our admiration of the care which characterizes the compilation of this history and its excellent series of illustrations.

#### CHEMICAL WARFARE

Volume XIV which has been published recently, transcends anything that has yet appeared in one volume on the medical aspects of gas warfare. Although it deals with the problems presented by this new weapon, so far as they concerned the medical department of the United States Army directly, or through affiliation with its chemical warfare service, it constitutes a record of great scientific value, and is of exceptional importance in connexion with the organization of the service of defence and the treatment of gas casualties. Early in the war the United States military authorities realized the seriousness of this new weapon and in the introduction of poison gases was one of the most important military developments, and that no innovation since the introduction of gunpowder has revolutionized warfare to the same extent. So seriously did the American General Staff regard it that by the end of the war the United States machinery for the manufacture of poison gas was producing nearly double the combined output of Germany, France and England. More than 10,000 men were employed in the chief factories in addition to those employed in nine other factories throughout the country. At the time of the armistice 140 tons could be produced daily, and in contrast with this it is stated that

mining was manufacturing 50 tons daily when it started mesh warfare, its power of production gradually increased, owing to economic conditions, and that at the time of the armistice it could produce only a fourth of its amount.

The volume tells us the history of the activities of the chemical department in connection with the defensive measures against the new weapon, in three main sections: twenty-one chapters. The first section of four chapters deals with the organization and administration of gas service, the second also of four chapters with the chemical features of gas poisoning, and the third forming approximately half the volume, with experimental research.

The chapters of the first section are comparatively short of eighty pages, are of chief interest from a military and practical point of view. They deal with the organization of gas defence in the United States and with the American Expeditionary Force in France, the classification and methods of use of war gases, and the field arrangements for gas defence and for dealing with gas casualties. As early as November, 1915, the military authorities in Washington decided that the duty of providing defensive equipment against poison gases, in the event of its being needed, should be assigned to the chemical department, and the Surgeon General consequently appointed two medical officers to act as observers in France. Eventually in May 1917 he was definitely entrusted to supply during the period ending June 1918 with gas masks, 8,500 sprayers and 1,000 oxygen cylinders. A field supply section and overseas repair unit and a training section for gas defence were then organized under Lieutenant-Colonel W. P. Chamberlain of the Medical Corps to whom an establishment of 144 officers, 1,637 other ranks was allotted. A large number of British gas expert officers arrived in Washington in November, 1917, under Major Auld of the British Military Mission and were posted to the training section. In January 1918 the whole of the training section was added to the engineers of the National Army and July of the same year a chemical warfare service was organized, to which the whole personnel administration and organization of gas defence were transferred from the chemical department. In this respect the development of gas defence in the United States followed much the same course as in the British Army.

A feature of the United States organization in the field was the appointment of a medical gas officer to each division, although none was actually appointed until the 1st of June, 1918, and it was not till October that all the divisions had their medical gas officers. The duties of these officers were to institute measures for instructing and training medical personnel in handling gas casualties and to rank and file in first aid to direct the work of mobile degassing stations, collect and forward pathological specimens to the army laboratory and generally control the management of gas casualties from the commencement of gas attacks until all had been degassed and disposed of, each division according to its position in line, in a sector or in a back area, one of its four field hospitals was assigned for the reception and sorting of gas cases, or for slightly gassed and convalescents or as a reserve in case of a gas attack. A scheme for sending two agencies, gas teams, consisting of an officer, two nurses, two orderlies from each base hospital to these field hospitals did not materialize, as it was strongly opposed by the chief surgeon of the First Army, who considered that resources of the army were insufficient without them and that a field hospital was not a suitable place for female nurses. A plan for allotting to each corps three mobile hospitals of 1,500 beds each as gas evacuation hospitals was also not carried out but a provisional army gas hospital was established at the end of August 1918 naturally five such army hospitals were allotted for the reception of gas casualties with 200- to 550-bed capacity. Medical services were also employed in an experimental establishment near Chantmont.

Nine pages only are given to the chapter on the classification and use of war gases, and the remaining chapter of the first section of the volume is a reproduction of the reports of divisional and other medical gas officers,

together with a history of the office of the medical director of the chemical warfare service with the United States Expeditionary Force, Lieutenant Colonel H. L. Gilchrist, who had spent some time studying defensive gas measures in the British gas school at Rouen. A useful plan of a degassing gas tent and an account of its organization and employment are given in this chapter. There are some interesting statements regarding self-inflicted gas burns and malnourishing. The United States mortality from gas poisoning was 17 per cent of the cases treated as compared with 3 to 4 per cent in the British and French armies. This cannot be attributed, says the report, to better treatment, but was "due wholly to the fact that a large number of reported gas casualties were suffering from other causes." In one field hospital a board of medical officers examined 281 cases under treatment for gas poisoning. They found that only 90 had actually been gassed, and the others were returned to duty. "Many men," the report goes on to state, "have claimed they were gassed in order to get out of the first lines" and again "it is believed if the true facts were known concerning our gas casualties, that they would not be over one third those actually reported."

The second section of the volume on the clinical features of gas poisoning records much the same facts as the corresponding chapter in the *British Medical History of the War*. The greater part of the section, however, is a detailed statement of 107 necropsies on men who died from gas poisoning illustrated with many coloured and other microscopic and microscopical specimens. It concludes with a chapter on statistics of gas casualties in which we are told that 70,552 or 31.45 per cent, of the 224,089 battle injuries in the United States Army were due to gas, and that 1,221 or 0.82 per cent, of the 13,691 deaths from these under treatment for these injuries were attributed to the effects of gas. Of the gassed cases, 27,711 (599 deaths) were from mustard gas, 6,834 cases (66 deaths) from phosgene, 1,843 (7 deaths) from chlorine and 577 (3 deaths) from arsenic poisoning. The nature of the gas in 33,557 cases and 546 deaths was not reported. These figures demonstrate the remarkable protection eventually provided against chlorine for when chlorine gas was first let loose against us in April and May 1915 it is estimated that fatal results occurred in 5 per cent of the cases under treatment as compared with only 0.28 per cent in the United States Army in the later years of the war after protective measures had been fully developed. An analysis is made of the after results in 3,014 gas casualties, from which it appears that 54.34 days was the average period of treatment in hospital and was greater in mustard gas than in chlorine or phosgene cases. 79 of the 3,014 cases had died but only 30 of these deaths were obviously due to the effects of gas. They occurred within ten to thirty days after the attack except in three single cases (after 61, 113, and 1,955 days respectively). Of the 30 deaths, 24 were from the effects of mustard gas. The incidence of pulmonary tuberculosis after gassing was studied, but the conclusion was that there was no evidence to show that the death rate from this disease in the United States had been in any way affected as the result of gas poisoning during the war.

The remaining section of the volume fills some 400 of its 876 pages. It consists of an account of the experimental researches in gas poisoning, by various workers in the United States, only one of its thirteen chapters being devoted to the work of the experimental gas establishment in France. The section is however of great pathological interest and is elaborate in its details of experiments on animals and human beings with various gases. An appendix of some seventy pages contains a statement of the gas defence equipment supplied, an account of interallied conferences and lectures given in Paris to the divisional medical gas officers, and other detail.

As a book of reference on the defence aspect of chemical warfare the volume has no equal in medical literature. Its practical value to the military medical services will be found in the comparatively short first section. It is beautifully printed and illustrated and its price 3 dollars makes us wonder how a volume of its size can be published at so small a cost.

### WINDOW GLASS SUBSTITUTES AND SUNLIGHT THERAPY

THE Council on Physical Therapy of the American Medical Association has issued recently a valuable report on tests of new window glass substitutes for which the claim is made that they allow the passage through them of the short wave lengths of light forming the ultra violet end of the spectrum. Four kinds of material were tested: vitaglass and coming glass, which are said to be true glasses, celoglass, composed of fine mesh screen filled with an apparently celluloidinous preparation and flexoglass, a thin, rather loosely woven cloth treated with a paraffin-like substance. Four tests were employed. The first was photography of the spectrum for clear glass, this at once shows the length of the spectrum transmitted. But as this is only useful for plain glasses, other methods had to be adopted for crinkled glass, since this scatters the rays. For testing crinkled glass a modification of the Hilger monochromatic illuminator was used. Into the eye piece of the instrument a thermopile was inserted connected with a delicate galvanometer, and the material to be tested was inserted within the eye piece close up to the thermopile, so that scattering effects were negligible. Further, a new instrument, the pyrehometer (fully described in the report), was employed to obtain continuous records of the intensity of the sunlight in connexion with the biological tests. This instrument is so sensitive that with it diffuse light can be measured as well as direct sunlight, and when used in connexion with a special amplifying unit it is sufficiently sensitive to measure the variations of twilight.

In the biological tests chickens were used, because experience has shown that they are well suited for an investigation of this kind. Chickens react to an environment deficient in ultra violet rays. They suffer from a leg weakness which is like, if not identical with, mammalian rickets. The chickens were housed in the same laboratory, feeding was identical and controlled. Six groups of birds were tested with different lighting—some with the special glasses, others with ordinary window glass. The condition of the epiphyses was determined by radiograms. With some of the birds exposed to ordinary window glass the well known characteristic posture of the rickets affection was obvious even a week before the x-ray photographs were taken, those exposed to the special glasses escaped.

The results of the investigations encourage the belief that materials for glazing windows are now available which do not possess the fault of ordinary window glass in excluding the health giving rays of sunlight. This belief (the report states) is particularly engendered because in the biological tests the cages did not have a southern exposure, and they were, moreover, of such a size that the chickens were not compelled to remain in the sunlight area. A comparatively small amount of exposure to sunlight, even during the winter months

at the latitude of Boston ( $42^{\circ} 22' N$ ) has a decidedly beneficial effect. Coming glass and the clear vitaglass are as transparent to the visible rays as window glass. Celoglass and flexoglass, on the other hand, are not transparent, but the data furnished by the experiments show their comparative value for use in solariums and for animal housing in cases where transparency is not essential. Both these substitutes are less expensive than ordinary window glass, but flexoglass is more affected by atmospheric changes than celoglass. The wax coating of the flexoglass has a tendency to soften in hot sunshine, and dust may then adhere which is not easily washed off.

This feature—the effect of dust—merely incidentally mentioned in the report, is a vital factor in the success or failure of any special glass or glass substitute. It will be remembered that efforts were made not long ago to persuade the London County Council to use one of these types of glass for the classroom windows of the county schools. The proposal was negatived owing to the belief that the installation would be of no effect. Windows in London are so speedily gumed with dust, both within and without—within from the heating apparatus and without from the smoky atmosphere—that daily cleaning would be needed to preserve the special properties of the glazing material. So that, however effective these new glasses may be in permitting the transmission of beneficial ultra violet rays, town dwellers cannot hope to reap any advantage from their use until such time as the campaign for smoke abatement has won substantial success. For the stock breeder in the country they are available, but he has at his disposal unlimited command of such sunlight as falls upon these islands if only he will not pen up his beasts and birds in buildings during the hours of daylight.

### PSYCHIC BACK NUMBERS

WHE among the higher mammals the degree of intelligence varies so greatly is not very easy to explain. Essentially it must be due to heredity and the primary urge or impetus peculiar to the species. It is doubtful whether the subject can, or ever will, be taken any further, but it is legitimate to ask what are the associated biological conditions. According to Professor Fleury, the astonishing superiority in intellect of man over other mammals is in part brought about by the long period of pre-natal life. He even believes that the increase of man's intelligence which has occurred comparatively recently when measured in geological time is related to a lengthening of the period of gestation from 220 to 280 days.<sup>1</sup> This extension, he suggests, has made possible a greater growth of brain before birth, while the delay in the hardening of the skull permits an increase in the cerebral volume during infancy. Dr. Ennle Devaux, who has recently<sup>2</sup> returned to a discussion of the psychic backwardness of the higher vertebrates as compared with man, calls these latter *amies psychiques*, which may perhaps, be roughly translated as psychic back numbers. To explain their inferiority of brain, despite in some instances apparent superiority of organization, Dr. Devaux points out that in all such animals either the muscles or the digestive apparatus are voluminous. To relieve this increase in volume a vast supply of blood is necessary, and the determination of the blood supply to the muscles or digestive organs leads to a comparatively poor supply to the brain. The cerebral cells cease to multiply as soon as

<sup>1</sup> *Physical Therapy Report on Window Glass Substitutes*, Journal of the American Medical Association 1927, vol. 83, No. 20, p. 1562.

<sup>2</sup> *Nature* 1927, vol. 118, p. 760.  
*Revue Scientifique* 1927, no. 2, p. 36.

their function is fixed so that for large brain development the organism requires in Dr Devaux's opinion, as in Professor Fleury's, a long period of intrauterine life combined with a long quiescent existence as an infant. In illustration of his views and to explain certain apparent contradictions Dr Devaux sets himself to answer the following questions: Why is the tiger not more intelligent than the cat? Why is the dog more intelligent than the sheep? Why is not a bird more intelligent than man? Why is the elephant inferior to us in intelligence? It is unnecessary to go into the arguments used by Dr Devaux in answering all these questions—it will be sufficient to take the case of the elephant which enjoys an intrauterine life of eighteen to twenty months—does not reach adult life until 22 or 24 years of age, and at first sight therefore, ought to be more intelligent than man. In the elephant the association of ideas attains a complexity which seems to surpass even that of a dog and its memory is remarkable. Nevertheless its recreation is infantile, and for these reasons says Dr Devaux it is exclusively a vegetarian feeder its osseous and muscular structure is gigantesque it has in hyperrophy on its tree. Evidently Dr Devaux is no vegetarian, since he states that animals living on vegetable foods which are longer of digestion have on this account to ration the supply of blood to their brains. Consequently the carnivorous dog is almost as intelligent as the elephant and far more intelligent than the sheep notwithstanding the mere sixty-three days of its gestation and the comparatively short period of puppyhood. When to its vegetarian habits we add the enormous bulk of the elephant and the prodigious development of its nose we have quite enough to account for the insufficient supply of blood to the brain which has prevented the elephant from attaining the human standard of intelligence. Dr Devaux's conclusion is that different syndicates of cells in the organism are in continual conflict on the subject of blood supply. This conflict in certain cases places the organ of thought in a state of functional impotence as the result of defective nutrition and thus explains the poverty of intelligence in animals which seem more favoured than we are in other directions of organization.

Dr Devaux was moved to write his article apparently because of a remark of Pierre Delbet that one of the advantages of transformism is the possibility it offers of explaining the origin of the huge development of the human brain. For this reason it may not be out of place to refer to the argument of Professor C Lloyd Morgan in a paper read earlier this year to the Aristotelian Society on emergent evolution. There is something of the nature of a boom in emergent evolution at present and Dr William Brown in a recent lecture at Oxford invoked its aid in proof of the existence of God. Professor Lloyd Morgan is concerned to show that while he claims that some evolution is by discrete or emergent advance each step introducing something new he does not deny the existence of resultant evolution. In resultant advance, says Professor Lloyd Morgan the conditions are such that there is homogeneous continuity. In biology the mechanist says that all processes and products from first to last from the not living to the living organism are susceptible of resultant interpretation and that further research will in due time resolve problems which today present difficulties. The believers in emergent advance find that there are modes of behaviour in the clustering of events within the living organism that are not

deducible from that which obtains in the not living. Their attitude is: Resultant advance in plenty—is much as can be proved, but not a few residual matters which bear witness to emergent advance. Professor Lloyd Morgan fears that the concept of emergence may lead to wild use of the phrase as a popular catchword and instances the possibility of people talking of the emergence of the elephant or the mongrel and the emergence of polydactylism in ants. He endeavours to make his meaning clear by suggesting that biological inquiry includes both natural selection and genetics—that natural selection is such deals with variants, that some variants are weeded out in the struggle for existence, leaving others to survive—that such an elimination is a resultant effect—that the origin of variations is a subject for genetics and that this or that variant may be the outcome of either resultant or emergent advance. It may be therefore, that Professor Lloyd Morgan's hypothesis can assist in answering Dr Devaux's question: Why is an elephant inferior to man in intelligence?

Dr Devaux in discussing his question: Why is the dog more intelligent than the sheep? speaks of the unequal strain imposed on the organism by different diets and he attributes in part the stupidity of the sheep as compared with the dog to the fact that digestion in a carnivorous animal is finished in twenty-four hours while a herbivorous animal requires three or four days according to one authority or even eight days according to others. The small intestine of the dog is only three times the length of the body that of the sheep twenty-eight times and in Dr Devaux's argument the blood supply differs correspondingly in profuseness. A study by Dr William A Thomas of Chicago of the Eskimos of Northern Labrador and of Greenland has some bearing on the points we are considering. He made his investigations in the course of the MacMillan Arctic expedition of 1926 and has given to his report the title: Health of a carnivorous race although only the Greenland Eskimo now lives entirely on meat he has no available source of vegetable food. Dr Thomas was chiefly concerned in making a cardiovascular and renal survey of the people. He did not find evidence of any excess or renal or vascular disease in this meat-eating race. Moreover the Greenland Eskimo derives sufficient vitamins from his food to protect him from scurvy and rickets. In Labrador however contact with civilization has led to a distressing condition. As food is abundant the inhabitants have learnt to cook their food. Moreover, the Moravian missions and the Hudson Bay Company with the best of intentions, sell to the natives such provisions as dried potatoes, flour, canned goods, cereals and cereal products. Dr Thomas says that scurvy, rickets and scurvy rickets are consequently universal in children the gums are black the teeth drop out and there are hemorrhages of the skin and mucous membranes. In adults there are rheumatic pains, stiff joints and fatigue. Notwithstanding months of constant sunlight, rickets seems almost universal. Except for these diseases, introduced by civilization the Eskimos are a healthy race leading a life of great physical activity and constantly exposed to great dangers and hardships. We have no reason to suppose that the small intestine of the exclusively meat-eating Eskimo is shorter than the intestine of a vegetarian but it is interesting to learn that a race can be so healthy on a purely meat diet. We learn also that in some cases at all events, the introduction of a diet in part vegetarian—especially of the canned variety—is not attended with risk.

## SIR JOHN GOODWIN

The Queensland Branch of the British Medical Association entertained Lieutenant-General Sir John Goodwin, K C B, late Director-General of the Army Medical Service, to dinner on June 16th, three days after his arrival in Brisbane to take up his appointment as Governor of Queensland. Dr H V Foxton, the president of the Branch, was in the chair, and 104 members were present. In proposing the health of Sir John Goodwin, Dr Foxton voiced the gratification of the Branch at his appointment as the representative of the King. Sir John Goodwin, in reply, expressed his thanks for the very hearty welcome given to him, both as a fellow medical practitioner and as Governor. He said that he looked forward with pleasure to his term of office, and keenly appreciated the kind reception he had had from the members of the Branch. Apart from his official work in Queensland, he added he was still greatly interested in medical work and in the activities of the British Medical Association, of which he was a member. He would support the interests of the medical profession so far as it lay in his power, and do what he could to assist those of the Queensland Branch.

## INJECTION TREATMENT OF VARICOSE VEINS

A good deal of interest has been shown by general practitioners in the comparatively new method of treating varicose veins by the injection of sclerosing substances. For those wishing to pursue the subject further a small work has now been written by Dr A H Douthwaite,<sup>1</sup> who briefly described the method in our issue of September 25th, 1926 (p 554). In his preface the author says that, with the exception of certain conditions which are detailed, he knows of "no varicosity in the limbs or anal canal, no matter how severe which will not respond to the sclerosing effect of a suitably chosen solution." The advantages claimed are that post-operative embolism and the discomfort of a general anaesthetic are avoided, and that the treatment is ambulatory and there is no loss of time to the patient. The method owes its inception chiefly to French workers among whom the names of Sicard, Gauguier, and Genuy are most prominent. Various solutions have been tried chiefly sodium salts including the carbonate, citrate and silicate, as well as such substances as biniodide of mercury, glucose, iodine, and solutions of quinine salts. Dr Douthwaite's experience is based on the neutral hydrochloride of quinine, of which he has now given over 2,000 injections. He employs for preference the following formula: quinine hydrochloride 4 grams, urethane 2 grams, distilled water 30 c.c.m. This can be boiled, and possesses strong antiseptic properties; 1 c.c.m. is injected on the first occasion to test the susceptibility of the patient to quinine, and 2 to 3 c.c.m. can be used at subsequent sittings. The patient is placed in a suitable position to distend the veins and the skin cleansed with spirit. The needle is inserted into the vein, and 1/4 to 1/2 c.c.m. is injected, and the process repeated two inches farther up the limb. The immediate effect is to produce a slight transient cramp and swelling of the vein. Subsequently some itching and tenderness may be felt, but this is dissipated by movement. Brimming from leakage at the site of puncture may occur. The quinine may be tasted by the patient immediately after injection and in those possessed of an idiosyncrasy tinnitus may follow. Inting giddiness and gripping hypogastric pain may be felt if menstruation is proceeding. Ague may be precipitated in malarial patients. The local effect of these solutions is to cause irritation of the endothelium of the vein followed by clotting, but it is claimed that this chemical clot is firmer and more adherent with less

tendency to detachment. As contraindications are cited pregnancy (quinine in particular should never be used), old or recent phlebitis, in which injection may light up the infection, and heart disease with imperfect compensation. Injections are inadvisable in cases of renal disease, uterine fibroids or during menstruation. The method is simple, and the results so far recorded are excellent. Whether they will be as good when the method comes into general use it will be interesting to see. Those intending to use it would do well to see it carried out before trying it. Criticizing the method from a purely scientific view it would seem that more investigation is necessary. It is said that this chemical clot is firmer and more adherent than the septic clot. What we would like to see are microscopic sections of its life-history, its formation, its extent, and time of its resolution. Does the end of the clot form a solid plug, or does it trail off? The fact that quinine can be tasted in some cases immediately after injection suggests some permeability of the clot in the deep veins or in the main radicle, and the question arises whether, after repeated injections, the effect remains as local as is indicated. The vogue of the transparent sill sticking has given a great impetus to this form of treatment and it is to be hoped that those intending to employ it will first master its principles, otherwise we can foresee some awkward complications following its use by inexperienced hands.

## ANNUAL REPORT OF THE MINISTRY OF HEALTH

The eighth annual report of the Ministry of Health has now been published in a separate volume, and supplements the report of the Chief Medical Officer of the department to which we have referred at some length in our last two issues. While the present report follows for the most part the lines of its predecessors, changes have been made in the order in which public health services are dealt with. The subjects treated include, under the heading of public health, international health work, general health questions, such as mental deficiency, registration of nurses and voluntary hospitals, sanitary administration, the inspection and supervision of food, infectious diseases, infants and child welfare, supervision of the blind, housing and town planning. Local government and local finance are considered at some length, and sections are devoted to the administration of the Poor Law, National Health Insurance and contributory pensions, and the Welsh Board of Health. Most of the matters treated in this report have been dealt with in official publications, noticed by us at various occasions during the year, but a new feature in the present issue is a valuable retrospect of the principal changes in the organization and development of services since the Ministry of Health was established in 1919. This affords an interesting survey of the administrative procedures which play an important part in the improvement of the public health. Accounts are given by general inspectors of the local administration of the Poor Law during the year—a revival of a former practice. The Report of the Ministry is published by H M Stationery Office at the price of 5s. net.

## ALCOHOL AND THE LEAGUE OF NATIONS

The question whether alcoholism has an international aspect which properly brings it within the sphere of the League of Nations led to one of the most spirited discussions of the present Assembly in Geneva. The proposal to make the alcohol problem the subject of study by the League was brought forward by the Foreign Minister of Belgium. Denmark, Czechoslovakia, Finland, Poland, Sweden. The basis of it upon the fact that it was not had been obliged during the last few years to take measures to prevent the smuggling of alcohol.

<sup>1</sup> *The Injection Treatment of Varicose Veins*. By A H Douthwaite. D. Mitchell, London. H K Lewis and Co. Ltd. 1927. (6s. 6d.)

frontiers so that the need for international agreements in this matter had been felt further, that the taking up of this question would be a logical sequel to the work already done by the League in respect to the traffic in alcohol in mandated territories and to the protection of women and children. In the work on this latter subject alcoholism and prostitution have been found to be largely interdependent. The chief opponent of the proposal was M. Loucheur, the French delegate who, while describing the joy and rapture he owed by good wine," nevertheless betrayed his anxiety lest the impression should get abroad that France was pro-alcohol. M. Loucheur grew almost lyrical in praise of the wine when it is red, and while professing respect for water drinkers declared that his respect was quite mingled by envy. It was during this eulogy that the President making a sudden gesture upset the water bottle on the table before him and drenched those in the vicinity. The delegates for Portugal and Italy also wine-producing countries warmly supported their French colleague but Mlle Rosenberg delegate for Hungary and president of the National Council of Hungarian Women said that the fact that her own country produced tokay would not prevent her from supporting strongly the action now proposed and she put it forward as an ascertained fact that women who took a glass of wine a day were unable to nurse their babies. But the noes had it? The Australian delegate the Hon T. J. Ley of Melbourne claimed that alcoholism could on no account be brought within the Covenant of the League. If the plea was made that because the occasional abuse of drink produced disease alcohol came under Article 23 (the League will endeavour to take steps in matters of international concern for the prevention and control of disease) why should not milk come within the scope of the League since impure milk caused tuberculosis or tobacco began excessive smoking caused nicotine poisoning? On the other hand said Mr. Ley, if the proposal came forward as an extension to all and sundry of the action which the League had taken on behalf of native races in mandated territories he thought it was even less justifiable. He also emphasized the point that prohibition in several countries was still in an experimental stage and that action by the League at this juncture would smother the progress of a social experiment as well as interfere with the liberty of the State. The Hon Philippe Roy of Canada said that a wave of prohibition had at one time threatened Canada but all the provinces except Prince Edward Island had reverted to wine. He could not support the proposal especially if it included wine which as a doctor he considered a form of nourishment and not a poison. Professor Burckhardt the Swiss delegate urged that while the League was not required to act in such a matter under the terms of the Covenant there was nothing to prevent it so acting but any action must be at the unanimous desire of the members which was certainly not forthcoming. Dr. W. E. Elliot M. P. the British representative suggested that the proposal be withdrawn and submitted in a new form to a subsequent assembly and eventually the proposal, headed by the Foreign Minister for Sweden agreed to this course. Evidently even such a modest proposal as to set up a League committee to study the subject and collect information brings unsuspected lions from their lairs.

#### DEFICIENCY DISEASES

There is a tendency to consider that deficiency diseases are not synonymous with vitaminosis. Recent experimental work on farm animals has shown however that not only is the list too narrow a view to take but that in fact diseases may be due to deficiency of certain non-vitaminous salts of iron, iodine, manganese, calcium, phosphorus and so on—minute quantities of which are

essential for the well being of all animal organisms. Thus certain tracts of valuable land in New Zealand are useless owing to the lack of iron in the soil. Sheep pastured on these areas show signs of anemia develop lameness, and become emaciated owing to this single deficiency. This can be seen in all parts of the world. One of the most striking examples however has been found in the Union of South Africa where two serious conditions of cattle—*lammekte* and *steyfsakte*—have long puzzled the local authorities. Recent investigations at Onderstepoort Veterinary Research Institute by Sir Arnold Theiler and his colleagues have shown that both may be traced directly to a lack of phosphorus. The latter disease is in fact due to this condition alone and so is a true deficiency disease. *Lammekte* however, is rather different. It is the form originally given by the South African pioneer farmers to a fatal disease of cattle characterized by symptoms of paralysis and paresis, principally of the locomotor system. The first clue to its causation was discovered by Sir A. Theiler in 1915 after observing a natural infection following the deliberate ingestion of skeletal carcasses. Experimental feeding with the same debris produced the disease and the idea of a toxicogenic prophage was at once considered. This was found to be a specific antibiotic bacillus *Parabotulinus* very closely related to the well known *Bacillus botulinus*. The next step was an inquiry into the cause of the depraved appetite (osteophagia) which impels the animal to eat carcass debris which it would otherwise shun and this was found to be due to the phosphorus-deficient vegetation causing a phosphorus starvation in the eat-le. Both can be entirely eliminated by the addition to the food of substances—such as bone-meal—rich in phosphorus, a proceeding which not only causes quickened growth in young animals but a considerable increase in the milk production in adults. These cases only indirectly affect human medicine but their fundamental importance is very great as great probably the discovery of vitamins a few years ago.

#### A LINK

HARRY BURRILL has written a delightful book full of illustrations on *The Platypus* (*Ornithorhynchus*). He has been on terms of intimacy with the animal for a period of twenty years, is well acquainted with its ways and has written its biography in a manner which evokes a more lively interest than that derived from the contemplation of one dried and bottled specimen. Introduced to science in 1799 by Dr. George Shaw the first specimen to reach Europe were looked on with suspicion, commonly they did, by way of the Indians was there was an inclination to class them with Eastern manna and other work of art of the crafty Chinese. When this prejudice was overcome the animal formed material for controversy among the bigwigs of science for nearly a hundred years. Being a furry animal it should by right be a mammal but Shaw had stated that it laid eggs and Home discovered that it had no nipples. The St. Hilaires in France thought it laid eggs while Richard Owen considered that it produced eggs which were hatched within the body. Meckel who discovered that mammary glands were present held that the young were born alive and Blainville held the same view. Blainville from an examination of the skull concluded with a genuine penetration that the animal laid eggs. Finally Caldwell settled the question by observing a female platypus in the second stage of parturition with the eggs in the act of passing through the dilated cervical canal. Not only does the animal build a nest and brood like a

Eleven-halftwelfth Paper of the Director of Marine Education

The University of Illinois, Urbana, Ill.  
R. 12711

lion, it suckles its young after the eggs are hatched, possesses a common cloacal aperture like the lizards, and is furnished with channelled spurs and poison glands resembling the fangs of the serpent. It and its relative, *Ichidna*, are the sole surviving representatives of a race of great antiquity, which in Mesozoic times represented the aristocracy of the animal kingdom and were the lords of creation. At the present day it burrows peacefully in the banks and noses in the sandy bottoms of Australian rivers, and although zealously protected by the Australian Governments, it still retains some of its ancient defensive habits. Of these the most remarkable is that exhibited by the female of blocking up her nesting burrow with a series of mud barricades, or "pugs," as a protection against the ingress of enemies that no longer exist, the pugs being dug through whenever she leaves her nest, and replaced on her return.

#### REGULAR MEDICAL EXAMINATION

In our issue of September 26th, 1925 (p. 575) we noted the formation in Manchester of a company under the name of Family Medical Services, Limited, which had arranged at Lloyd's the "Anchor" policy for providing for the middle and professional classes a proportion of the cost of doctors' fees. We have now received from the company particulars of a scheme for what is called "regular medical overhauling" of subscribers. We find ourselves again obliged to complain of some lack of lucidity in the documents issued by those responsible for this undertaking. According to the latest prospectus, "Family Medical Services and Regular Medical Examination Association have no interest in the financial results of the schemes, and are merely to receive a percentage which has up to date fallen short of actual expenditure." Fees for regular medical examination are "a question of some difficulty," but it is suggested that the fee for examination of the first member of the family should be 7s. 6d., and for each other member 6s. The examination is to be carried out twice annually, and the result to be sent to the Regular Medical Examination Association in the form of a report by the doctor. The report is to state either that the person examined is in sound health, or that he is advised to have treatment under one of five headings—medical, surgical, dental, ophthalmic, or institutional. Whether, as a result of the report, Family Medical Services then steps in and urges the patient to have treatment, partly at the company's expense, is not stated. Anyone wishing to take part in the scheme is to write to the R.M.E. Association expressing a wish to subscribe for half-yearly medical supervision, and agreeing to pay the fees mentioned above. We are not told whether it is to be inferred that the R.M.E. Association—without any financial interest in the scheme—takes a percentage of the seven-and-sixpenny and six-shilling fees of the doctor, or whether Family Medical Services is the connecting link and provides the percentage upon which the Regular Medical Examination Association exists. We suggest that both bodies might be advised to employ an expert draughtsman to edit their prospectuses. In the meantime, those who wish to investigate the schemes may communicate with the head office, 20, York Street, Manchester, or the London address, 1 and 2, Great Winchester Street, E.C.2.

#### THE ROYAL VETERINARY COLLEGE

An appeal for £50,000 is being made on behalf of the Royal Veterinary College, Camden Town, of which Professor Frederick Hobday has been recently appointed principal. It is estimated that a sum of £85,000 is required to place the college in a satisfactory position in respect of building

and equipment. A grant from the Development Fund of the Treasury of a sum not exceeding £35,000 has been sanctioned, subject to the condition that an equal sum at least must be provided otherwise. In an interesting historical note accompanying the appeal it is recalled that the study of veterinary science only started in England in 1791, when the College was founded. The first students were enrolled in the following year, and a diploma was granted to those who passed an examination after having attended for eighteen months. During the first four years of its existence the College relied on donations and subscriptions (supplemented by students' fees) for the funds necessary for acquiring a site, building operation, and remuneration of the staff, but in 1795 Parliament sanctioned an annual grant of £1,500. This grant was withdrawn about the year 1815. The College, however, continued to develop, and in 1876 the curriculum was extended to three years, in 1893 a fourth year of professional study was added. Between 1890 and 1894 nearly the whole of the accumulated funds of the College, amounting to over £15,000, were expended on building and equipment. Through lapse of time the present buildings have become inadequate in extent, many being actually unsafe and beyond repair. Bearing in mind the national importance of the work carried on at the College, it is surprising to learn that in France and Germany the maintenance grant for the veterinary colleges in a single year before the war exceeded the total amounts given by successive Governments for veterinary education in England and Wales during the last 100 years. Help was, however, received recently from the Development Fund for the erection and equipment of the Research Institute in Animal Pathology, but no portion of it was applicable for improving the buildings devoted to education. The annual maintenance grants by the Ministry of Agriculture for research and education are also not available for capital expenditure on the College buildings. In view of the national loss inflicted by animal diseases there is urgent need of more intense and better directed study, and it is to be hoped that there will be a generous response to the present appeal. Over 6,000 cases are dealt with in the outpatient department annually, and thus invaluable opportunities are available for the education of students if only the buildings can be rendered adequate. The Earl of Northbrook is acting as treasurer of the fund.

THE museum demonstrations at the Royal College of Surgeons of England, for advanced students and medical practitioners, will begin on Friday, October 14th, when Sir Arthur Keith will show results of recent research into the reproduction and growth of bone. His second demonstration, on October 21st, will be on rheumatic and other changes in joints, illustrated by specimens from the Sturgeons Collection, now in the museum of the College. His third demonstration will be on specimens illustrating congenital dislocation of the hip and other joints. The demonstrations will be given at 5 p.m. on each day in the theatre of the College, in Lincoln's Inn Fields.

THE Huxley Lecture will be delivered at Charing Cross Hospital Medical School on Thursday, November 24th, by Sir Archibald Garrod, K.C.M.G., F.R.S., Regius Professor of Medicine in the University of Oxford. The subject has chosen is "Diathesis."

THE Rockefeller School of Biochemistry in the University of Oxford will be opened by the Right Hon. Viscount Cave, K.C.M.G., Lord Chancellor of England and Chancellor of the University, on Friday, October 21st, at 3.30 p.m.

## INTERNATIONAL HEALTH ORGANIZATION

[FROM A CORRESPONDENT AT THE ASSEMBLY OF THE  
LEAGUE OF NATIONS]

THE interest at the annual meetings of the League of Nations at Geneva in September shifted further and further from the Assembly itself, which is little more than a platform for oratorical speeches to the various Commissions, among which the overwhelming of the League's various activities is distributed. It is in the Commissions that the more vital discussions take place, and there also the effective resolutions are framed. The endorsement of these resolutions afterwards by the Assembly in what is called plenary session is a mere formality. The work of the Health Organization comes before the Second Commission, which this year is presided over by Senator Dandurand of Canada. The discussion occupied the greater part of two days. The members of the Commission include at least three medical men—Dr. Walter Elliot M.P., representing Great Britain, the Hon. Philippe Roy representing Canada and Professor Calvo Mackenna, representing Chile.

*The Car's Work*

The discussion on the work of the Health Organization was introduced by Sir RAMASWAMI AVAR, one of the delegates for India who referred to the welcome innovation made during the last year by the Health Committee in the appointment of expert assessors who took part in the work of the League in an advisory capacity. The appointment of assessors from countries as distant from Geneva as Australia and Japan showed how far the Health Organization extended. From the Bureau of Epidemiological Intelligence at Singapore weekly reports on the health conditions in 137 ports of Asia, Australia and East Africa were transmitted to a number of wireless stations. A more recent development was the weekly distribution of epidemiological information from the wireless station at Noumea, in Ceylon. The Sleeping Sickness Commission had terminated its work and had produced a report of much interest. The interchanges of public health officers on study tours had proceeded and a further development was the organization of international health courses, each course lasting about seven weeks and consisting of lecture, discussion and practical demonstrations. The first of such courses was held in Paris during the early months of this year and the second will be held in London in November and December. Sir RAMASWAMI AVAR also referred to the report of the Malaria Commission. As one result of the Commission's labours courses had been organized at the Faculty of Medicine Paris, the London School of Hygiene and Tropical Medicine, and the Institute of Maritime and Tropical Medicine Hamburg. A laboratory course of some four weeks duration was followed by two months' work in certain malarial districts of Italy, Spain and Yugoslavia. The expenses incurred by attendance at these malarial courses were a charge on the League Health Budget and the courses were necessarily limited to medical officers engaged in military work in Government employ in different countries. Another phase of the League's health activities had been the International Rabies Conference held in Paris in April last which had afforded the first opportunity for directors of institutes from all parts of the world to meet and compare experiences of the results obtained with various modifications of the original Pasteur method in use in their laboratories. Two other important activities touched upon by Sir RAMASWAMI AVAR were the study of health insurance by an expert commission which met in April last and decided on its programme of inquiry and the study also by an expert commission of infant welfare in certain selected countries. This latter inquiry was now proceeding in seven European and one of two Latin American countries were being taken to include areas with high and with low infant mortality and rural and urban districts. Sir RAMASWAMI AVAR concluded his survey of the health activities of the League with an assurance of the hearty co-operation of India.

*Health Mission to Latin America*

An account was given to the Commission by Professor CALVO MACKENNA, delegate for Chile, of the mission recently carried out in certain Latin American countries by the Health Committee of the League. The president of that committee, Dr. T. Malen, and the medical director, Dr. Ryckman, visited Latin America, mainly in connexion with a survey of the causes of infant mortality (a matter of special interest to Latin American countries in view of the sparseness of their populations) but they included general health conditions within their scope. Professor MACKENNA described the gathering at Montevideo last June of delegates from six South American countries to study the medical causes of infant deaths. The conference was presided over by the Minister of Industry of Uruguay, and attended by the President of the Republic. Investigations were set on foot and later there will be another gathering and an exchange of views on the results of the inquiry. Professor MACKENNA also announced that the Argentine Government was supporting a proposal to establish at Buenos Aires, under the auspices of the League, an international health centre for infant welfare. He went on to plead for a further extension to South America of the system of interchanges of public health personnel with the granting of scholarships to Latin American medical men to enable them to follow the courses of higher education in public health at Buenos Aires and Rio de Janeiro. There was a proposal from the Brazilian federal public health service that an international leprosy research centre might be established, also under the auspices of the League. A Brazilian philanthropist, Dr. Guinle, was prepared to contribute £2,000 a year towards the expenses of such a centre. Another proposal was to inaugurate in South America a centre for researches into the sero-diagnosis of syphilis. This proposal was made by the Instituto of State Hygiene at São Paulo which was willing to meet a proportion of the cost. Another South American enterprise mentioned by Professor MACKENNA was the sending over to Europe from Uruguay of a medical deputation to study the system of national health insurance with a view to the introduction of the system into Uruguay. Yet a further instance of the interest in public health in South America was the engagement by the Chilean Government of a Japanese expert from the Imperial Institute for Research on Nutrition in Tokyo for the purpose of inaugurating a similar service in the Central Health Department of Chile.

In some general discussion on the health work of the League, Mr. NAGAI of Japan said how much Japan appreciated the advantages of the interchange of experts. Mr. VEJERSKY of Czechoslovakia described how his country was tackling the problem of social health insurance and Baron NEVEST of Hungary, Herr BREIT-CHIEF of Germany, and Mr. VESCOVICH of Portugal reported various public health measures in their respective countries.

Dr. W. F. ELLIOT M.P. of the British delegation, spoke of certain aspects of the work of the Health Section, which so far had not been fully brought out. Among these was the work on the investigation of disease, particularly cancer and malaria. The cancer investigation was still in its infancy but he could imagine no field in which the comparative method would yield more useful results. In the investigation on malaria great work had already been done. Malaria was a disease which had a special interest for the League of Nations in view of the League's work in connexion with refugee and migration problems. The example of England which although a malarious country with many marshes and sluggish rivers had been able to eliminate indigenous malaria was encouraging for less severely afflicted. Another instance of the value of the health work of the League was in connexion with the standardization of dangerous drugs. It was a matter for justifiable pride that the official requirement all over the world with regard to many drugs was simply that they should conform to the standards set up by the League of Nations Commission. Finally, Dr. Elliot suggested that the health work of the League, with its opportunities for research and adventure, helped the League to make an appeal to the new generation not

less thrilling than the pomp and circumstance of war had made to the old.

The Commission adopted unanimously two resolutions. The first of these expressed gratification at the continued development of the international activities of the Health Organization, and in view of the recommendations made by the International Pacific Health Conference held at Melbourne at the end of last year, regarding work which might be done in connexion with the study of health problems in the Pacific area, asked that such work might receive the early and full consideration of the Health Committee. The second resolution was in the form of a blessing upon the extension of the work of the Health Organization to the countries of Latin America, commending to the consideration of the Council and the Financial Committee the several proposals mentioned by Professor Mackenna as having been put forward by the health authorities of Argentina, Brazil, and Uruguay.

### *Health Budget of the League*

The Fourth Commission approved the Health Budget of the League, which estimates a total expenditure for 1928 of 1,381,333 Swiss francs, or about £55,000. Toward this amount, however, the Rockefeller Foundation subscribes 388,695 francs, so that the total contribution of the League to health services is below £40,000. The salary of the Medical Director is 53,000 francs (£2,120). The proposed new work in Latin America, however, will involve certain supplementary votes.

The very interesting discussion on alcoholism, which took place also in the Second Commission, is the subject of a note elsewhere (p. 558).

## *Novæ et Vetera.*

### MEDICAL TRADITIONS AND EXPERIENCES OF A VICTORIAN NOVELIST

There is much of interest to medical historians in the life of G. P. R. James by Mr. Stewart M. Ellis. The novelist, so dear to our grandfathers but now almost forgotten, was the grandson of Dr. Robert James, patentee of James's powders, and the son of Pinkston James, who practised as a physician in George Street, Hanover Square, during the latter part of the eighteenth and earlier part of the nineteenth centuries. Old Robert James was a character. The fellow townsman, school-fellow, and lifelong friend of Dr. Johnson, he resembled that great type in the quickness of his temper, in scholarship, and in the frankness of his dealings. Inimitable to a degree, Dr. Robert would allow no one to contradict him save the mighty Dr. Samuel, and the latter, though he had no great opinion of the other's pharmaceuticals, nevertheless enjoyed his society and applauded his general skill in medicine. Boswell records Johnson's reception of the news of James's death in 1776, and is surprised at his apparent coldness. "Ah! poor James!" was all Johnson said, though later, "when we were in the chaise, he said with more tenderness, 'Since I set out on this journey I have lost an old friend and a young one. Dr. James and poor Harris' (meaning Mr. Thrale's son)." Afterwards, of Gilbert Wilmshurst he wrote: "At this man's table I enjoyed many cheerful and instructive hours, with companions such as are not often found—with one who has lengthened and one who has gladdened life, with Dr. James whose skill in physic will be long remembered and with David Garrick." "No man brings more mind to his profession" was another remark of Johnson's when discussing the inventor of the powders.

These were patented in 1745 when James filed a specification of a pill and of a powder. The ingredients of the latter were afterwards found not to tally with those of the doses sold for James by Newbery, the bookseller. Newbery sold two doses for half a crown "with good allowance for those who buy them for charitable uses." The public bought and swallowed not knowing what they swallowed, and were healed by their medical attendants. No less

a man than Horace Walpole encouraged the use of James's powders with his high if fantastic social prestige. The gentle Cowper attributed to them the recovery from illness of Mrs. Unwin, and an eminent physician who applauded their employment in the army believed them to be composed of powdered human cranium. Hutton was commonly held to be one of their ingredients, which are given by the encyclopaedias as calcium phosphate and antimonious oxide. Powerfully sudorific, they fell into disuse when fevers ceased to be treated with depressant, but they linger in the *British Pharmacopoeia* as pulmonary stimulants. The secret is indeed out, though they were long handed on as a "mystery" in the James family.

How far G. P. R. James benefited by this lucrative secret is not clear, but he lived at a high rate, as his grandfather had done. Monetary difficulties taking him to the United States, he was British Consul in 1853 at Norfolk in Virginia, and here he encountered the yellow fever, "an African disease unknown in the New World till they began importing negroes." As late as 1891, when the late Dr. Charles Creighton published his exhaustive work on epidemics, the fever was traced to filth in the slave ships, and especially to bilge water, but the true cause—the mighty bites of the *Stegomyia fasciata*—was unknown. James, in a letter to his publisher, speaks of himself as "surrounded by swamps and marsh miasm" and "eaten up by mosquitos and black flies." Yet the mosquito remained unsuspected, though it is curious to find that the great visitation of yellow fever in Norfolk in 1855 was heralded "by a plague of peculiar flying insects, partly yellow in colour." The *Stegomyia* mosquito, however, is a black insect, with silver markings on its thorax. Many of James's friends died of the disease, and some of them exhibited grievous symptoms, notably Mrs. Huron, wife of a commodore, from the pores of whose face blood oozed so quickly that it was useless trying to wipe it away. Norfolk was a city of desolation comparable to that which reigned in London during the Great Plague.

When the British consulate was transferred to Richmond, James, during his first winter there (1856), encountered an epidemic of diphtheria, then supposed to be a new disease. A well-known Southerner, Preston Brooks was its first victim. He was supposed to have been killed by his physician, who, to quote Charles James, son of the novelist, "insisted, against the patient's instincts, on surrounding his throat with powdered ice, which caused coagulation and death in a very short time. Before long diphtheria was epidemic in Richmond. When my father [G. P. R. James] hid it, his throat was cleared out repeatedly with lunar caustic." This treatment, the son thinks, may have stayed off suffocation. Two years later he believes, the disease crossed the ocean, creating panic in Europe. The principal epidemics were in particular towns, and in England diphtheria was known as "Boulogne sore throat." It was especially prevalent here in the winter of 1858-59, being regarded as a new disease of transatlantic origin, though it is really no novelty.

To G. P. R. James's own medical traditions and experiences should be added those of his wife, whom he married in 1828, she was the daughter of Honoratus Leigh Thomas, well known in his day as a leading London practitioner. He was President of the Royal College of Surgeons in 1809 and again in 1838. As a very young man he had come to London with an introduction to John Hunter, who characteristically bade him call at 5 o'clock in the morning, when the visitor found him busy dissecting insects. He became Hunter's dresser and a pupil of Cruikshank, whose daughter he married. Leigh Thomas was Hunter's near neighbour, and must have been deep in his traditions. We may well suppose that he told his son-in-law first about the great man, but beyond letting his reader know that he had long been familiar with the history of Sir Theodore Broughton's death by poison and practically of the trial that ensued, in which John Hunter was a principal witness, James seems to have made no use of the John Hunter legend. In his novel *Sir Theodore Broughton*, or *Laurel Water*, published in 1848 by Smith, Elder & Co. he missed a grand opportunity, for instead of describing Hunter's personality of which he must have been abundantly aware through his father-in-law, he contented

<sup>1</sup>The *Story of the Life and Adventures of G. P. R. James*. By S. M. Ellis. At the Cassell Press. 1927.

himself by alluding in his preface to the cautious and wholly admirable evidence of "the famous" John Hunter at the trial of Captain John Donellan for the alleged murder of his ward, young Sir Theodore Broughton, in 1781. John Hunter refused to commit himself to the assertion of other medical men to the effect that Broughton had died of a poisonous dose of laural water and merely insisted that the appearances at the post mortem examination amounted to putrefaction and no more. Hunter thus very honestly refused to condemn Donellan in his evidence, and incurred the sarcasm of the judge, who indulged in comments on the valuelessness of medical evidence. James in his preface shows himself on the side of Hunter, and expresses the opinion that Donellan was not the murderer. In the novel he tells the story of Broughton's death and shows what was probably Donellan's actual share in it, but of the trial he makes only a cursory mention on the closing page of his immense story.

George Payne Rainsford James wrote some eighty romances much read by his contemporaries, but also much blighted, for he opened most of his stories with "a solitary horseman" or two horsemen—onto the hero the other a king in poor circumstances—riding over a solitary landscape. So eloquently had the horse beginning become associated with his name that G. P. R. James in our fathers' days, was generally dismissed as a kind of joke by those patient and omnivorous novel readers, and since the sixties has fallen into undeserved neglect. Mr. Stewart Ellis is to the nineteenth century what the late Austin Dobson was to the eighteenth: he wears Dobson's mantle and is a scholarly and admirable biographer. But it is a question whether even he has read all James wrote, though his bibliography of James's works, which includes over ninety items, is a model of what such things can be. I would be interesting to know if G. P. R. James ever treated a medico-legal theme as in his novel above mentioned and in one other, *The Commissioner*, which deals, interestingly no doubt, with lunacy.

## Ireland.

### IRISH FREE STATE ELECTION

The following members of the medical profession are among those elected to the new Irish Parliament:

Sir James Craig (Dublin University) Independent  
Dr. T. Hennessy (Dublin City South) Government  
Dr. Miles Keogh (Dublin City South) Government  
Dr. P. J. O'Dowd (Lancaster) Fianna Fail  
Dr. J. J. O'Reilly (Cavan) Government  
Dr. James Ryan (Wexford) Fianna Fail  
Dr. Sean Tubridy (Galway) Government  
Dr. Ward (Monaghan) Fianna Fail  
Dr. Vincent White (Waterford) Government

It will be recalled that Dr. Thomas Hennessy, Irish Medical Secretary of the British Medical Association, was successful at the by-election in the same constituency shortly before the dissolution of the Dail. He is to be congratulated warmly upon repeating his success at the General Election on September 15th. There has been much delay in declaring the results of the polling in many constituencies, owing to the very tedious method of counting and elimination which accompanies proportional representation.

### MEDICAL INSPECTION OF SCHOOL CHILDREN IN NORTHERN IRELAND

An efficient system of medical inspection and treatment of children in primary schools is one of the great advantages conferred by the Education Act of Northern Ireland. The Ministry of Education in its report states that during the year 1926-27 there was a marked growth of interest on the part of local education authorities in this subject. This may be attributed not only to the united efforts of the Ministry of Education and the Ministry of Home Affairs to awaken in the local education committees and the general public a sense of the importance of this branch of the work, but also to the desire of the committees themselves to ascertain the extent of the

problem presented by the afflicted child. Moreover, a spirit of health rivalry has been aroused by the gratifying results achieved in those areas where medical inspection has been introduced at a very early stage. Some education committees had, in fact, addressed themselves immediately to the investigation of the physical condition of the children, but others, less convinced of the necessity for action, or somewhat apprehensive as to the cost, had hitherto appeared reluctant to take any serious steps towards the fulfilment of these duties. Apart from the education authority for the county borough of Belfast, the Ministry has now received reports of the working of schemes of medical inspection of school children in (1) the combined areas of Larne, of Lisburn and Belfast (rural), and of Antrim, (2) the combined areas of Londonderry and Limavady, of Coleraine and of Magherafelt, (3) county Fermanagh. These reports show not only that the necessity for systematic medical and dental inspection is great, but also that this need has hitherto been almost entirely unsuspected by the public. At first the medical officers of the local authorities encountered opposition on the part of both pupils and teacher, who did not understand the purpose of medical inspection. Since it has been discovered that these inspections have brought to light physical defects which were previously unsuspected, however, opposition has rapidly disappeared and parents have been anxious to have their children examined. Not only this, but it has also been found that parents generally have shown commendable alacrity in taking steps at their own expense, so far as has been possible, towards the remedy of the physical defects disclosed as the result of the medical examination of their children. The reports of the medical officers in the above mentioned areas show that the work so far accomplished though as yet necessarily incomplete, has been very valuable. All sections have been roused to the sense of their responsibility, and there is a growing eagerness to have the work continued and extended.

### MEDICAL TREATMENT FOR INSURED PERSONS IN THE FREE STATE

At the annual meeting of the delegates from the National Association of Insurance Committees (Ireland) which was held recently in Dublin, a memorandum was approved in connexion with the provision of medical treatment for insured persons in the Free State. The association, having considered the final report of the Committee of Inquiry into Health Insurance and Medical Services desires to place on record its considered views on certain recommendations therein as follows:

1 The association is convinced that the only satisfactory solution of the problem of the provision of adequate medical treatment for the working class and their dependents—whether insured person or otherwise—in Scotland, Eireann lies in the immediate adoption of a national scheme of medical services on a contributory basis comprehensive in scope and freed from all association with Poor Law administration.

2 The association emphatically agrees with the suggestion made in the final report that for various reasons—mainly financial—the immediate adoption of such a comprehensive scheme is not practicable. Not only is the care of the public health one of the first duties of government but true national economy lies in the pre-emption of the working capacity of the people. Economy secured at the expense of the people's health is a prodigal waste of a national asset.

3 The association agrees that unless a national scheme embracing insured persons as well as others is immediately adopted the provision of medical benefit for insured persons is an urgent necessity.

4 The association cannot commend the proposals for medical benefit adumbrated in the final report as satisfactory to insured persons. In its opinion the very limited advantages which they might confer on certain classes of insured persons are not commensurate with the sacrifices which insured persons generally as well as their employers are called upon to make.

5 The association considers that any scheme of medical benefit to be satisfactory to insured persons must comply with certain essential conditions: (a) It must be completely dissociated from Poor Law administration. (b) The treatment provided must be thoroughly efficient which involves agreement with and the full co-operation of the medical profession. (c) Being on a contributory basis operation must be open to the free criticism of the persons whom it serves and it must provide convenient machinery for the investigation of complaint. It must therefore

be locally administered by bodies on which the contributors as well as the other interests concerned are represented.

6 The Association strongly urges on the Government the immediate adoption of a comprehensive national scheme of health services for insured persons as well as other members of the community unable to provide adequate medical treatment in illness, on similar lines to those advocated by the Irish Public Health Council and the County Councils' General Council.

7 The Association protests strongly against the proposal to deprive insured contributors of the right of representation, guaranteed to them under the National Insurance Act 1911 which is involved in the recommendation for the abolition of Insurance Committees.

## Scotland.

### EDINBURGH UNIVERSITY CHAIRS

WITH regard to the chair of forensic medicine and the chief police surgeonship in the city of Edinburgh, rendered vacant by the recent death of Professor Harvey Littlejohn, steps have been taken for conducting the duties of the latter post, to which an interim appointment has been made of Dr Douglas Keir. Dr Keir has, for the past five years, held the post of assistant to Professor Littlejohn in both appointments. The appointment to the chair of forensic medicine in Edinburgh University is in the nomination of the Crown, and no appointment has yet been made. In regard to the chair of medicine, Professor G. Lovell Gulland, whose resignation was recently intimated to the university, has been reappointed to continue in office during the forthcoming winter session. The resignation was to have taken effect on account of the Professor's retirement, on attaining the age limit, from his position as physician to the Royal Infirmary of Edinburgh. The relinquishment of wards at the age limit does not, however, take effect before December of the present year.

### JAMES MACLEZIE INSTITUTE FOR CLINICAL RESEARCH, ST ANDREWS

The syllabus for the winter session of 1927 at the James Maclezie Institute for Clinical Research, St Andrews, has now been issued. Addresses on clinical subjects, followed by discussions, to which all practitioners are cordially invited, will be given on Tuesday afternoons, at 4 p.m., while on Friday afternoons, at the same time, meetings are held for clinical discussions. On Tuesday, October 4th, the introductory address will be given by the honorary director Mr A. M. Ramsay on ocula manifestations of gastro-intestinal disorder, and the ensuing discussion will be opened by Dr W. C. Souter, lecturer on ophthalmology in the University of Aberdeen. Dr J. B. Orr, director of the Roylett Research Institute, Aberdeen, on October 11th, will deal with the influence of diet on the physiology of the stomach; he will be followed by Professor Haining of the University of St Andrews. On October 18th Professor John Fraser will consider superficial pyrexia as an aid in the differential diagnosis of abdominal disorder, and in the following week Dr R. O. Adamson will describe dyspepsia as met with in general practice. Professor D. P. D. Wilkie will deal with gall-bladder disease and gall stones on November 1st, and Professor J. J. Charters, on November 8th, will discuss pharmacological principles in their relation to common gastro-intestinal ailments. The clinical significance of haematemesis will be the subject of an address by Dr E. Matthew on November 15th, and the surgical aspects of gastric and duodenal ulcer will be considered by Professor Archibald Young on November 22nd. The early symptoms of cancer of the stomach will be described by Dr Edmund Spriggs on November 29th, and Sir George Lenthal Cheate, on December 6th, will lecture on some recent views about carcinoma as applied to the colon. The last two lectures of the session will be given respectively by Professor Robert Muir on December 13th, who will discuss the dissemination of malignant disease, with special reference to the abdomen, and by Professor John Mainoch on the following Tuesday, who will enumerate some pitfalls in the diagnosis of acute abdominal conditions. The subjects dealt with

on the Tuesday afternoons will be found in our Diary, published weekly in the SUPPLEMENT, and the syllabus of the course may be obtained from the secretary at the institute.

### NURSING SERVICES IN SCOTLAND

At the opening of a fete held in the grounds of the Atholl Palace Hotel, Pitlochry, on September 15th, the Duchess of Atholl, M.P., Parliamentary Secretary to the Board of Education, delivered an address in which she outlined the position of district nurses in Scotland. The fete was held on behalf of the funds of Queen Alexandra's Scottish Nursing Memorial Fund and of the Pitlochry District Nursing Association. Her Grace said that there had been a great advance in the nursing facilities provided throughout Scotland, and that to-day it was recognised that skilled nursing was just as essential for the restoration and preservation of health as skilled medical or surgical treatment. A great impetus had been given to this movement by the Queen Victoria Nursing Institute. In more recent years the institute had given its nurses training in such matters as infant welfare, school medical nursing, and other health interests lying within the scope of the local authority. The Queen's nurses were the most highly trained type of nurse in the country, and the Government recognition provided for useful co-operation between statutory bodies which had powers to promote the health of the people in different ways and voluntary associations which dealt with many problems of health. Some 700 Queen's nurses were at work in different parts of Scotland, there were trained at considerable cost, and in recent years the institute had been faced with an annual deficit. A further increase of fully 50 per cent of nurses was required to meet the needs of Scotland. The object of the Queen Alexandra Fund was to endow the institute and enable it to carry on its great work, as well as to provide a lasting memorial to Queen Alexandra, who had done much to develop and encourage nursing during her lifetime.

### SCOTTISH QUARTERLY STATISTICS

The more outstanding features of the vital statistics of Scotland during the second quarter of 1927 are a birth rate of 20.6 per thousand, a marriage rate of 6.5, and a death rate of 12.9. The death rate is 3.2 below the previous quarter and is the lowest yet recorded in Scotland for the second quarter of any year. The actual number of deaths during the three months was 15,891. In the larger burghs taken individually, the quarterly death rate ranged from 14.9 in Coatbridge, 14.8 in Dundee, 14.5 in Glasgow, and 14.0 in Perth, to 9.7 in Kirkcaldy, 9.9 in Ayr, 10.1 in Clydebank, and 10.2 in Hamilton. The quarterly death rate in England and Wales was 11.0 per thousand, and in Northern Ireland 15.9 per thousand, the former being 1.9 less, and the latter 3.0 more, than the equivalent Scottish rate. The infantile mortality rate in Scotland for the quarter was 78 per thousand births, which is a low figure. Of the total deaths 13 were from enteric fever, 110 from measles, 45 from scarlet fever, 269 from whooping cough, and 70 from diphtheria. The deaths from influenza were 432, from encephalitis lethargica 27, and from cerebro-spinal meningitis 44. The deaths from tuberculosis, all forms, numbered 1,346, being 8.5 per cent of the total deaths in the quarter.

## England and Wales.

### GUY'S HOSPITAL

Among the chief matters of interest in the Guy's Hospital report for 1926 is to be found in the appendix to the treasurer's report. King Edward's Hospital Fund desired that hospitals should extend the principle of costing in various departments of their work, so as to show in greater detail the expenses of the various departments. In the appendix to the treasurer's report a preliminary attempt has been made to introduce a detailed costing system. From this it is shown that in a total of £100 per occupied bed the most expensive item is £70 for

salaries and wages. This is not surprising since it is stated that it takes approximately three people to look after two patients or, in round figures, 600 patients in hospital require 900 people doing working directly or indirectly on their behalf. The report shows also that certain departments such as the venereal diseases department are very expensive in comparison with ordinary out-patient treatment. It is suggested that in future, when the expenses of out-patient treatment in different hospitals are compared it should be noted against each hospital whether a whole-time venereal department is maintained or not. In a table on the unit of cost in various departments it is interesting to note that the cost per patient in the paving ward was £7 18 4d as compared with £10 4s in the general wards. This apparent anomaly is explained by two reasons. In the first place the paving ward is charged only with maintenance and bears no charges for administration, secondly, the average occupation of beds in the paving ward is only twelve days whereas in the general wards it is twenty. The actual cost per occupied bed in the paving ward is £219 as compared with £185 in the general wards. About 10 per cent of the cost per bed appears in the analysis as "unanalysed expenditure." The report contains an appeal for the endowment of medical education and research and subscriptions are invited to a discretionary fund which can be allocated between the hospital and the school in proportion to their respective needs.

#### CRUMPPALL INFIRMARY, MANCHESTER

Mr. A. H. Burgess, professor of clinical surgery in the University of Manchester, opened, on August 4th, new buildings at Crumppall Infirmary, with which he had been previously connected first as house-surgeon in 1893 and subsequently as visiting surgeon for ten years. The total cost of the present extension scheme including the provision of equipment was about £20,000 and the addition comprise three operating theatres, two recovery rooms, x-ray and storage rooms and a dispensary. Mr. Burgess in an address praised the enterprise and public spirit of the Manchester guardians in recognizing the responsibilities introduced by the modern advances in surgery by the provision of facilities which might be termed the very latest word in hospital construction and equipment. The co-operation of Poor Law hospital with voluntary hospitals in general hospital work was also the subject of favourable comments by speakers at the ceremony. Crumppall Infirmary was established in 1877 and has over 1,400 beds, of which the average number occupied is given as 1,259. A training school for nurses was instituted at the commencement of its existence. Beds are available for private patients.

#### LABORATORY ASSISTANTS' ASSOCIATION

The second conference of the Pathological and Bacteriological Laboratory Assistants' Association was held at the end of last month in the Department of Pathology of the University of Cambridge, and was attended by members from the Gold Coast, South Georgia, Shanghai, and from all parts of the British Isles. An official welcome was accorded by the Vice-Chancellor, who congratulated the association on the valuable share it was taking in the advance of scientific knowledge. During the conference the Junior Greenfield prize and medal were presented to Mr. E. B. Brain of Birmingham for colour drawings on pathological subjects. The Sims Woodhead medal was presented to Professor Lorrain Smith the first president in recognition of the great service he had given since the formation of the association in 1912. The subject dealt with at the conference included the manufacture of small pox vaccine in Shanghai, the dietary of rabbits and guinea-pigs, antagony and symbiosis of bacteria, the development of parasitology, the preparation of plague vaccine and tissue culture technique. A comprehensive exhibition of laboratory work and apparatus was arranged and visits were paid to the various centres of interest in the neighbourhood. The conference dinner in Trinity Hall was attended by 104 members and guests including the Vice-Chancellor and Professor G. H. Nuttall.

#### LIGHT TREATMENT IN BERMONDSEY

A new institute for light treatment was opened in Bermondsey in June, 1926 at the rear of the tuberculosis dispensary. Two large rooms for light treatment are provided one for men the other for women each room is fitted with a small dressing room, and is under observation by a nurse and a doctor's room. The mercury vapour lamps employed have long leads, so that they may be taken out into the adjacent open yards when the weather is propitious thus enabling treatment to be given in the fresh air. Overheating inside the rooms is prevented by large folding doors, which can be kept open except in the most unsuitable weather. During 1926 treatment was given to 341 patients, the total number of attendances being 10,416. Many patients came from the tuberculosis dispensary, and others from the maternity and child welfare clinics, a large number had been sent for treatment by general practitioners. Patients with definite tuberculosis comprised 27 per cent of the total number treated, while cases of debility and malnutrition formed 37 per cent, the great majority of the latter—debilitated children—came as contacts from the tuberculosis dispensary. In his annual report for 1926 Dr. P. King Brown expresses his belief that light treatment will benefit to a greater extent the people of northern countries, where the natural sun is deficient, than those from southern Europe and the tropics. Dr. D. M. Connan the clinical tuberculosis officer, who is in charge of the light treatment, emphasizes the importance of regular attendance, and reports that children who come from very overcrowded homes make slow progress; he thinks that light treatment in such cases can only counteract in part the results of bad housing conditions.

#### ROYAL INSTITUTE OF PUBLIC HEALTH

A course of lectures on the health of the nation will be delivered at 37 Russell Square, W.C.1, on Wednesday afternoons, at 4 p.m., from October 12th to December 14th inclusive under the auspices of the Royal Institute of Public Health. The first lecture will be given by Dr. Saleeby, on sunlight for childhood, and the second by Professor S. J. L. Cummins, on tuberculosis as a social disease. Professor Haldane will describe some disease conveyed to man from animals and Sir Henry Curran will deal with osteoporosis as a problem of childhood. The present situation in regard to housing will be discussed by Dr. F. L. Fremantle, and the subject of a police as regards the milk supply will be treated by Professor R. Stenhouse Williams. Dr. A. Dingwall Fordyce will lecture on the prevention of heart disease and Professor Blair Bell on the prevention of cancer. The final two lectures of the series will be given by Dr. L. R. Lempriere who will speak on the health of the public school boy and Professor F. W. Hope who will deal with the changed conditions of quarantine. These lectures are intended for all those interested in medico-social problems. The Harben lectures will be delivered in the lecture hall of the institute on October 17th, 18th and 20th at 4 p.m. by Professor R. Brunoghe, director of the Institute of Bacteriology in the University of Louvain who will take as his subjects The Twort-Herelle phenomenon and Some new research on relapsing fever. It is announced that the annual congress of the institute in 1928 will be held in Dublin.

#### ROYAL NORTHERN HOSPITAL X-RAY DEPARTMENT

A new x-ray department has been recently opened at the Royal Northern Hospital, London, the limitations of the old one having been corrected by rebuilding. The department now consists of a screening room, a dental room, a special radiographic room for the examination of the skeleton and a treatment room with the usual accessories. The latest type of x-ray tube has been installed this confers upon the operator a hitherto unattainable degree of immunity from danger. The screening and radiographic rooms have been equipped with a high tension transformer which is silent in operation. The cost of the new department has been approximately £2,500, of which there remains a sum of £900 to be raised.

## Correspondence.

### BRITISH DOCTORS IN MADEIRA

SIR,—Your reference to the position of British medical practitioners in Madeira (*SUPPLEMENT*, August 20th, p 118) prompts me to say, with your permission, that there is no tangible likelihood of the exercise of any powers the island authorities may possess in disturbance of the present status.

I am mainly responsible for the statements recently conveyed to our Embassy in Lisbon and to the General Medical Council in London, and I can definitely assert that the local councils too fully realize the need of British medicos among the steadily expanding influx of Madeira tourists and climate seekers to take any step harmful to this substantial source of their prosperity.

There is now no lack of reciprocity in Portugal, and I will by and by submit to you the necessary conditions for qualifying to practise in this country. The fees are light, and there is no power to exact special payments. Two British registered general practitioners now reside among their patients, and these still appeal to me in difficulties.

The trouble in 1866 concerned me personally when, though in charge of the whole British community at Funchal, I was abruptly cited to cease practising, and when in the same breath the druggists were warned against my prescriptions. I could probably have contested this ill-timed and ill-natured action, but, being fully equipped to face any reasonable examination, I elected to present myself in Lisbon as a candidate for the Portuguese diploma.

The competent medical authority in Portugal then centred in the Lisbon Board of Health, whose obstructive administration of an obsolete quarantine system had brought them country into notorious disrepute. This board, after protracted negotiations most ably conducted by Mr Robert Lytton (afterwards Indian Viceroy), and in spite of a positive order from the Prime Minister, rejected my application on the ground that I had not studied in Portugal. We quoted the reciprocity clause in the Medical Act of 1859 without effect, and the Prime Minister, losing all patience with his insubordinate medical corporation, published a decree abolishing the board, himself assuming its functions. This action met with general approval, and the defunct body has never been revitalized. Special permission was it once recorded to me to follow my profession at Madeira, and at my own request the concession in the original document was extended in effect generally to English physicians. This *modus vivendi* has lasted more than sixty years and will never be disturbed while my successors regard the national welfare and cultivate relations of unity with their Peninsular associates.

Those who come after me will find that I have done nothing to impair existing respect for British culture, and they will be fortunate indeed if they can justify a portion only of the attainments attributed to us, and expected of us as custodians and exponents of natural science in its local aspects. It is clearly due to the learned bodies whence we come to maintain the tradition of our comprehensive training and mental aptitudes—I am, etc.,

MICHAEL GRABHAM, M.D. LL.D., F.R.C.P.

Madeira Sept 5th

### "ETHER CLONUS" ALDEHYDE AND PEROXIDE

SIR,—The occurrence during the last year or so of several cases of so-called "ether clonus" at St Bartholomew's Hospital has caused me great concern, and I have been at some trouble to discover the cause. Cases were reported by the residents and others they did not conform to the cases of ether clonus that I had met with myself years ago. Most of the cases seemed to have occurred after a fairly long anaesthesia, not as in the cases I had seen. The first point I noted was that occasionally when giving the gas-oxygen-ether-chloroform combination the resultant mixture inhaled by the patient had a somewhat acid smell. At first I attributed it to faulty ether, and insisted on having the purest, but even then the same acid smell was noticed on occasions. I then consulted Messrs Duncan, Flockhart and Co, who at once gave me

every facility. They have been throughout of the assistance, and have at all times been most anxious and willing to help. At my suggestion they instituted a series of tests under the direction of Dr W. Inglis Clark, D.S., whose report may be summarized as follows:

#### Summary of Chemical Investigations

Two tests were used in estimating the aldehyde in ether-chloroform. (a) Contrast with caustic potash for two or three hours, when, if no colour was visible, it was assumed that the ether contained no aldehyde. (b) Nessler's solution added to the water obtained after shaking equal volumes of distilled water and ether or chloroform for two minutes in a separating funnel. The second method was found to be both accurate and comparative. The first method gave fallacious results with ether-chloroform due to the interaction of alcohol. The peroxide present was ascertained by the B.P. test for solution of potassium iodide. The experiments were carried out by passing nitrous oxide or oxygen or a mixture of the two gases through chloroform (a) or both, kept at a temperature of 40° to 50° C, and then examining the condensed liquid from the cooled gases, as well as the residue in the original vessels. The gases were passed through liquids for one hour and for three hours in each case. To variable ways in which the gases were passed through the liquids gave a total of twenty experiments, in each of which the amount of peroxide and of aldehyde both in the residue and the distillate was estimated. As a result it was found that after the gases had been passed for more than one hour through ether there was a distinct tendency to the formation of peroxide. In less than one hour there was usually none. In some cases there was a slight formation of peroxide if the ether was kept standing overnight and after a few days peroxide would develop in the ether. But the amount was usually about 1 in 100,000, and never exceeded 1 in 50,000. With regard to the aldehyde the amount detected was very small indeed, it never exceeded 1 in 80,000 and was often not more than 1 in 200,000. Standing overnight did not increase the amount of aldehyde.

As a result of these investigations it appears that when either oxygen or  $N_2O$  or a mixture of  $O_2$  and  $N_2O$  is passed through chloroform or ether, or through both, a certain amount of both peroxide and aldehyde is formed. This discovery—which I frankly admit was new to me—leads me to think that, although the amounts as shown by the tests are very small, yet we cannot neglect them at all. In consequence, as the tests were conducted under the best possible conditions, we should try to use as little ether and chloroform as possible when giving the gas-oxygen-ether-chloroform combination, and the distillate should be the purest obtainable.

I do not know whether the presence of this small amount of peroxide and aldehyde would be sufficient to produce the condition of "ether clonus," and, indeed, I hardly think that it would, but on occasion when I have noticed the acid smell that I have mentioned it appeared to me that there must be quite a large amount of some noxious substance present, and I have at once cut off the ether-chloroform and had recourse to gas and oxygen alone.

The impressions that I derive from this investigation are:

- 1 As peroxide and aldehyde are found, we should use as little ether and chloroform as possible.
- 2 The bottles containing the ether and chloroform should be thoroughly cleaned and sterilized every day.
- 3 As far as possible fresh ether and chloroform should be used for each case.
- 4 Whenever the acid smell is noticed the ether-chloroform should be shut off.

I feel that this matter needs a much fuller investigation, and I hope to be able to continue it during the coming winter, but have thought it wise to give this preliminary warning so that other anaesthetists may not only reap the benefit of this discovery, but be on their guard for any signs or symptoms that may help in the solution of the problem—I am, etc.,

H. EDWARD G. BOYD, O.B.E.,

M.R.C.S. (LOND.)

September 2nd

Senior Anaesthetist to St Bartholomew's Hospital

### CONVULSIONS DURING ANAESTHESIA

#### Atropine in Childhood

SIR,—It would be unwise to allow the suggestion of Dr Hornibrook (*September 10th*, p 471), that convulsions occurring during surgical anaesthesia are due to overdosage of atropine, to remain unchallenged.

To cite the atropine dosage for children alone at the Hospital for Sick Children, Great Ormond Street, a dose of 1/100 grain of atropine sulphate was given to a

administered to all children of four years and upwards before every operation until we found it wiser to administer the atropine by mouth instead of hypodermically. For some two years since the atropine has been given by mouth, this dose has been increased. The children take the atropine simply in two doses the first two hours before the operation and one second one hour before the operation the total amount being 1.80 grain for all children of 6 years of age and upwards. This does not cause convulsions.

As over 7,000 operations are performed at the above hospital every year the children never exceed 12 years of age and every operation being preceded by the dose of atropine already quoted it can be assumed that atropine is not the cause of the convulsions in question because these convulsions have not been observed by either myself or my colleagues on the anæsthetic staff—I am, etc.,

HAROLD SEXTON

Sir or Anne that is the usual for Sick Children Great Ormond Street

London W 2 S 1 1 b

#### 'A FORGOTTEN BY-FACTORY'

Sir—SMITH HENRY Hill Hickman was not, as Mr Winland Joyce says (September 10th p 471) "the first discoverer of the anæsthetic relief of pain." General anæsthesia is known centuries before his time but it was forgotten. Tom Middleton in his tragedy *Women Beware Women* (Act IV, Scene 1 1605 or thereabout) writes

I'll imitate the pines of old surgeons  
To this lethargy who ere they show their art  
Cast once a nap then cut the diseased part

As so often happens, the poet remembered and recorded what was forgotten by everybody else.

Anyone reading the surgical records of the thirteenth century must realize that the operations performed could not have been the successes they were if general anæsthesia was completely unknown. And in fact Guy de Chauliac (fourteenth century) has left this record

Some surgeons prescribe medicaments such as opium the juice of the moral hyoscyamus mandrake ivy black lettuce which send the patient to sleep so that the incision may not be felt. A new pouge soaked by them in the juice of the and left to dry in the sun when they have need of it they put this pouge unto warm water and then hold it under the nostril of the patient until he goes to sleep. Then they perform the operation.

Why the employment of general anæsthesia was given up and the memory of it quite forgotten by the medical profession are mysteries not easy to unravel. But probably the Black Death was responsible. So very many of the leading doctors including de Chauliac himself perished or the plague taking with them their newly acquired knowledge and almost without doubt, the general public disappointed and despairing lost all faith in the medical profession. This much is beyond question—while the thirteenth and early fourteenth centuries were bright with the new found triumphs in medicine and surgery the following centuries were almost hopeless. It was not till the nineteenth century that anæsthesia and sepsis came once more into their own. But it should not be lost sight of that the so-called discoveries of the nineteenth century were in actual fact rediscoveries. Most of the pioneer work done here had been done already—in the Middle Age—

I am, etc.

FRANK G. IATON

#### PAINLESS CHILDBIRTH

Sir—On page 35 of the *Epitome* of September 10th we summarized the experiences of two writers with Gwinn's method of rectal ether anæsthesia. Harris claims that the applicability of this method is much greater than that of scopolamine amnesia" is contradicted by the quotations he himself mentions. It appears the method is not to be continued more than ten or twelve hours (what appears then is not stated), and that it should not be begun only. I have continued scopolamine amnesia for six five hours and it has I believe been given for over 20 hours. It should be begun before the pains are severe, and deny the patient relief in the early stages as in

Catharine's method, is surely a stultification in part the term "painless childbirth."

Both writers emphasize inertia as contraindicating the ether method, in inertia scopolamine may be employed without hesitation since by producing sleep it preserves the patient's strength and gives the best chance of a natural birth.

Prophets given, scopolamine-morphine narcosis shows better results than "85 per cent pain greatly relieved" (Harran) and full analgesia in more than half the cases" (Nauditch). Harran says "there was no increase of forceps delivery", this is indeed "fine praise." Scopolamine gives an increased percentage of physiological deliveries—that is fewer forceps cases—because it obviates the use of instruments merely to shorten the sufferings or prevent exhaustion of the mother or to placate the relatives, it is especially useful in labours that are likely to be prolonged—that is difficult—in contradistinction to Nauditch's experience with rectal ether. This writer also says that the morphine may be repeated but this may entail danger to the child in scopolamine amnesia the morphine should be strictly limited to the first dose.

Continuing what Harran apparently implies it is my experience that scopolamine-morphine narcosis is eminently suitable for use in a private house and though it necessarily takes up much time and requires some experience to get the best results (which will not follow rule-of-thumb or unstandardized methods) it does not require "the service of a trained anæsthetist."

In the case of a falling birth rate which is in part due to the dread of the sufferings of childbirth it cannot be too widely known that scopolamine-morphine narcosis, properly given affords a method of relief which is safe, harmless, applicable to all cases, and can be used in the patient's own home—I am, etc.,

LESLIE W. S. S. P. C. H.

E. CUNNINGHAM PLUMPTRE

#### THE ABUSE OF CAESAREAN SECTION

Sir—The publication of Dr Henry Jellicot's paper under the above heading in the *JOURNAL* of September 10th (p 451) should be warmly approved by all who have experience of obstetrics and are anxious that a high standard be maintained in this specialty. With the statistics in the paper and the conclusions come to I need not dwell, as they are recognized as true and sound by all who are in a position and qualified to give an unbiased opinion. What I hope to do is to point out how this abuse often occurs, and suggest something for its control.

Caesarean section is a surgical operation and well within the scope of a properly qualified obstetrician's practice but general surgeons may also well claim (and do so) that it is within their province. But it is not apparently realized universally that the true obstetric question is the advisability or not of the operation in any given case. That question can only be decided after careful consideration and examination by an obstetrician—whether with or without the help of other surgeons is immaterial for the moment to the argument.

Now so long as practitioners (often anxious to get the troublesome case "off their hands") are willing to transfer these cases to institutions hospital or maternity homes regardless of what expert hands they go into so general surgeons attached to such institutions will prefer Caesarean section as the easiest way out of the difficulty to them according to their view. Consideration of the foregoing must point to the general practitioner as an important link in the chain of events leading to the results we are discussing. It is so easy to transfer cases into other hands and the responsibility is apparently over. The trained midwife is another link in the chain. She has no option in her legal duties but to call in a registered medical practitioner in cases of difficulty and local health authorities acting through their maternity committees (not to mention the Ministry of Health itself) see no difference between different practitioners called to the cases, which almost always require specialist attention.

Criticism so far—now the suggestion. The large share of the remedy is in our own hands. The profession as a whole must cultivate a "conscience" in obstetric

matters. Local bodies of the profession (the Local Division of the British Medical Association, obviously, in most places) should trench with no uncertain voice, in season and out, that obstetric complications are work for obstetric specialists. An obstetric tragedy should be looked upon as a reproach to the local profession, individually and collectively, unless they have enforced this principle. Thus a real public opinion will develop, and then the aim will be to place an obstetric surgeon on the staff of all institutions that take maternity cases. His opinion will then be available, whether he does the operation or not.

Incidentally the maternity mortality will be reduced as it has not yet been (Sir George Newman's Report shows there has been no fall in the last year). A difficulty has been a lack of practitioners with obstetric interests. On this point one would remark that there is no "money" in obstetrics alone as a speciality, but this is not the place nor the moment to deal with that difficulty—I am, etc.,

Norwich, Sept 15th

ARTHUR CROOK

### PREGNANCY AND GLYCOSURIA

SIR,—In reply to Dr. Howe's letter in the *BRITISH MEDICAL JOURNAL* of September 17th (p. 520), I beg to state that the possibility of the case being one of lactosuria has not been definitely eliminated. A rough and ready fermentation test was inconclusive, and could not be repeated as the condition did not return. I would point out, however, that lactosuria usually persists during lactation. Further, the amount of milk allowed under the "ladder diet" is too small to justify the appearance of lactose in the urine.

I agree with Dr. Howe that the case was not one of diabetes mellitus.

My object in publishing the case was to call attention to the possibility of disorders of carbohydrate metabolism in the toxæmias of pregnancy. Since reporting the case, however, I see that insulin has been used with success in the treatment of hyperemesis gravidarum, so that my idea is not altogether novel—I am, etc.,

Lisburn co Antrim Sept 19th

T. A. KEAN

### MEDICAL LITERATURE FOR KENYA COLONY

SIR,—With reference to the letter appearing under the above heading in the *Lancet* of June 4th, 1927, the Council of the Kenya Branch of the British Medical Association desires to express strongly its disagreement with the statement made therein, that the medical practitioners of Kenya would gratefully welcome gifts of fairly up-to-date books on medicine and surgery.

The fact is that the medical department of the colony maintains a medical reference library which is accessible to all doctors in the colony. This contains all the best of the most recent medical publications, and takes in the majority of the standard medical and scientific journals published to-day. Furthermore, it is probable that the private libraries of medical men in this colony would compare favourably with those of their professional brethren at home.

While grateful for the suggested vigorous generosity of the President of the Victoria League, my Branch Council feels that the statement that medical practitioners in this colony feel a pressing need for textbooks of medicine and surgery may be misconstrued into a reflection on their professional efficiency—I am, etc.,

J. B. CARRIE,

President Kenya Branch British Medical Association

Nairobi Aug. 21

### THE PATIENT AND THE PROCEDURE

SIR,—The letter of Dr. Alim Moss (August 20th p. 528) and Dr. John Campbell (September 19th p. 472) under the heading "Blood pressure" is worthy of attention.

Are we not in the days of clinical laboratory diagnosis and injection methods of treatment sometimes apt in our enthusiasm to think too much of the disease and not enough of the comfort of the patient? As a private practitioner of many years' experience I find that patients often object

to being constantly worried with needle puncture even the blood pressure test—necessary (in my opinion) and useful though it is—is received sometimes with a heated protest. To quote a personal experience I have once ordered a daily hypodermic injection of a small endocrine extract for fourteen days in succession. At the end of that time the backs of my forearms from the elbow to the wrist presented a series of red tender swellings these were not due to sepsis, as I was most careful to avoid.

Take, for instance, the Sippy regime for the treatment of acute gastric ulcer, especially as modified by H. C. Price's *Textbook of the Practice of Medicine*, 6th edition, pp. 505-6. The remarks of Beaumont and D. J. (Recent Advances in Medicine, third edition, p. 174) are very much to the point. Were I a sufferer from this disease nothing would induce me to submit to the treatment. In my opinion the Lenz method is much preferable and, I believe, gives equally good result.

The administration of the arsenobenzol compounds, colloids, vaccines, and many endocrine extracts in the puncturing the subcutaneous or intramuscular tissue—understanding them with fluid (the most painful part of the process). Are these unpleasant methods of treatment indispensable?—I am, etc.,

H. W. WEAVER, M.D. (Lond.)

West Looe Cornwall Sept 12th

### THE INTERNATIONAL CONTROL OF DRUGS OF ADDICTION

SIR,—The letter which appeared from Dr. W. I. Davis on this subject in the *BRITISH MEDICAL JOURNAL* of August 6th (p. 235) concluded with these words:

"The menace on the Continent is already very real and the medical profession in this country may be required to reach a decision sooner or later, as to whether the safety of and to the British Empire which may be attained from the prohibition of heroin may not be greater than the pain relief afforded to a few patients which some of us think may be obtained with codeine or morphine."

The injurious effects of heroin have not been so put in my experience as this letter suggests. The routine use of this drug to allay cough has always struck me as a sign of ignorance, since cough so frequently is the bright side of a malady, being Nature's way to help the in passages. If people, however, are becoming addicted to this drug for other purposes the sooner it is put off the better.

My purpose in writing is to go further, and suggest the introduction of some control over the use of morphine even for legitimate purposes, and by medical men.

Some years ago I was treating an elderly lady for a chronic cough which she had long suffered. She and her daughters said it was useless to do other than give her an injection of half a grain of morphine to which she was accustomed from her own cough. I protested that it was too much, and gave one-quarter grain then one-eighth more and finally as the cough persisted well as the daughters an additional one-eighth grain. Then ceased heavy sleep followed, and no awakening.

Another patient I saw through a bad attack of typhoid. When somewhat better I transferred the case to a friend as I was leaving Mentone. He at once gave morphine and seemed excited, and she died in a few hours.

A third case came lately under my observation. Her husband had a severe hæmorrhage from gastric ulcer. His doctor gave an injection of half a grain of morphine followed in the morning by one-sixth more. The patient never came out of comatose sleep which supervened.

This sort of thing appears to me to be going on to a far too great extent, and the consequences are in the presumption that it is the malady which is not the morphine. It is forgotten that half a grain of morphine to an enfeebled patient may equal to a much larger dose to a vigorous person, a principle which many medical men do not seem to realize.

Would it not be wise if some rule or law were introduced that no medical man should give more than a quarter or one-third of a grain of morphine on any day, without the confirmatory opinion of a colleague? We are dealing with a drug of great potency often to a patient of low vitality, and it should be the patient's fault alone if he fails to recover—I am, etc.,

T. J. HAYES, M.D. (Lond.)

D. W. CARRIE

## SOUTH AFRICAN NATIVE PRACTITIONERS

Sir—Your valued correspondent for the Union of South Africa in the *JOURNAL* of August 20th (p. 323), quotes without disapproval the opinion of the Hospital Survey Committee to the effect that the medical needs of the tribalized natives of South Africa will not be met by providing for an influx of natives into the medical profession and this because it is alleged, "the qualified native practitioner is rarely content to practise among his own people in their tribalized condition."

As only a very limited number of South African natives have as yet attained to the status of qualified medical practitioners (thanks largely to the fact that the right to finish their medical education in their own country is denied them) it is easy to misinterpret the accuracy or otherwise of the committee's contention as regards them all, and this has been done.

A writer to the *East London Daily Dispatch* goes over each one of them by name and shows that without exception they have all thus far preferred to go back to their own people to exercise the healing art. Even Dr Molema who is mentioned as an outstanding example of the supposed tendency is, I believe at work amongst his own tribe the European cases of his which have caused such a stir being not of his seeking and an almost negligible proportion of his patients. The writer referred to concludes his letter thus: "Consent with the foregoing. Dr Motobang the latest medical recruit, is showing the same preference for Basutoland. In the face of this clear record of the past, what justification then, is there for the allegation that native practitioners will 'drift to a large town'?"

I think, Sir, you will agree that in bare justice to the South African natives and in particular to those of them who are members of our profession and holding British qualifications, these facts should be published to let our agents—the supporters of the committee in its otherwise admirable report.

It is not always safe to argue (as the committee apparently has done) as to what an African will do, either from consideration of what a European would be likely to do in similar circumstances or even from consideration of what other Africans in another distant part of that vast continent have done and it is the considered opinion of many who have given much thought to the subject that the providing of facilities for the training of natives as medical practitioners would go a long way towards the solution of the medical difficulties of native South Africa—I am, etc.,

DAVID M. BROWN

(Lubwa Chin ali N. Rhodesia)

Annan Dumfriesshire Sept 12th

## BREATHEING EXERCISES WITH MOVING ARMS AND MUSCULAR INHIBITION

Sir—Dr Gittins (August 6th p. 239) rejects the view that a muscle elongated by some movement, during the movement, continues contracted or even becomes more contracted. Dr Gittins strives to differentiate between "tension" displayed by a muscle and the "tone" produced by a muscle. He agrees that the "tension" of the pectoralis major is increased as the muscle is elongated by such a movement as raising the arm from the side but he adds, "it is surely unwarrantable" to deduce from this that its tone increases or that the muscle is in a state of contraction.

"Tension" is a characteristic of inextensible tissues such as aponeuroses and tendons the tension they present depends on their fibres (white connective tissue fibres) not on their cells though the state of the fibres depends ultimately on the cells. Striated muscle when pulled on under certain conditions can easily be elongated if it presents a "tension" under such circumstances, this must be due to the state of the muscle cells. The connective tissue fibres in striated muscle and even the cells themselves can only come into consideration as a factor causing "tension" when the limits of the greatest elongation of the muscle possible in the intact animal are surpassed. The changes in the cells of the muscle tending to prevent elongation within the normal limits, can only be assigned to variations

in the osmotic pressure of the cells, which is delicately affected by nervous impulses.

This is the "tension" of striated muscle is the effect in muscle produced by its "tone" or by its "contract on" it is the effect of the nervous system acting on the muscle cells. The "contract on" of muscle is simply an exaggeration of its "tone"—of its "tonic contraction." The tension of muscle varies with its tone and, other things being equal the tone of a muscle varies with its length when elongated in a movement its tone and thus its tension are increased. A reflex arc determines this. Musculo spindles sensory in nature exist. When the muscle is elongated, these musculo spindles are pulled on and generate impulses which, running up the afferent nerve fibres to the cord, affect the cells sending efferent impulses to the same muscles. Thus, when a muscle is elongated its contraction must increase unless it is inhibited by some superior force. Palpation in the normal both in myself and in my dog, shows that such an inhibitory force does not come into play during movement, and the effects of strychnine poisoning the phenomena of Thomsen's disease and of the muscle "cramps" tend to support this conclusion. During movement muscles elongated do not become slack. On the contrary, the force exerted by muscles elongated during a movement increases throughout the movement the elongating muscles actively oppose and resist the movement, and in this way they guide the acting or maximally contracting muscles so that precise, "co-ordinated" movement results.

It has been supposed that the state of muscle during posture and movement is different. But active posture, as related with active movements, passive postures with passive movements or no movement at all. During active posture we are alert and ready for the impingement of external forces or to exert ourselves on some environmental appearance during passive postures we are incapable of such response. There may perhaps be different innervations of striated muscle nor medullated nerves may indeed supply some of the fibres. Such researches however cannot obliterate the results of even gross examination of the muscles in our own bodies as palpation gives the current teaching of to-day does not explain the results. It requires modification before it can satisfy the postulates of the physiological experiments seen in a larger world—I am, etc.,

W. J. YOUNG

## MENIERE'S DISEASE TREATED BY THE ELECTROPHONODE

Sir—The interesting and important case described by my friend Mr. Arnold Ferguson of Jersey in your issue of September 10th (p. 454) is one which is highly satisfactory in the treatment of this difficult condition.

I hasten to endorse Mr. Ferguson's remarks by my own experience in two cases one of which a young lady aged 21, was published in the *Practitioner* for last August. In this case the vertigo which was her chief complaint, disappeared entirely before the first fifteen treatments were completed and she has since spent a holiday in Switzerland, where she practised mountaineering without difficulty—I am, etc.,

London W1 Sep 17th

MACLEOD YEARSLEY, F.R.C.S.

## "THE MEDICAL REGISTER"—UNTRACEABLE PRACTITIONERS

SIR,—With reference to the letter which appeared in your issue of September 17th (p. 526), written by a practitioner who signs himself "Still on the Register," in regard to the list of practitioners from whom replies have been received to the inquiries sent out from this office, I have to say that, in the case of practitioners in regard to whom it is improbable that a certificate of death will be received owing to their having died abroad, it is the custom of the Council to send a registered inquiry in order to comply strictly with the requirements of Section 14 of the Medical Act of 1858. This has proved to be a very necessary precaution. In the case of eminent men who at one time practised medicine but subsequently have taken up other careers, their names are included in the list in the ordinary routine, but, before names are erased from the *Register*, it is customary for the list to be carefully scrutinized, and as far as possible every precaution is taken to see that the names of those whose addresses can be ascertained and who are known to be living are not erased.

Your correspondent suggests that the *Medical Register* might be checked with the *Medical Directory*. I desire to point out that this is invariably done, and if an alternative address is found in the *Directory*, an inquiry is forwarded to it. The publishers of the *Directory* used to be in the habit of inserting an asterisk before the names of those practitioners who had not answered the inquiry sent to them. This is no longer done, and the Council is not able to see whether the address inserted in the *Directory* is one which has been ascertained immediately before publication or not. I might add that not only is the *Directory* consulted, but every possible means of preventing omission is adopted. Inquiries are addressed to the Ministry of Health, to the British Medical Association, and, if there is any indication that the practitioner has gone to the Dominions, the Colonial Medical Registers are searched, and no name is erased from the *Register* until considerable trouble has been taken to establish communication with the practitioner if still alive.

The following is a copy of Section 14 of the Medical Act, 1858, and it will be observed that the Council is under no obligation to do anything further than to send an inquiry to the registered address, but it does in fact make every reasonable effort to ensure that names shall not be erased if it can be avoided.

*Duty of Registrar to keep the Register correct.* "It shall be the duty of the Registrars to keep their respective Registers correct, in accordance with the Provisions of this Act and the orders and regulations of the General Council, and to erase the names of all registered persons who shall have died and shall from time to time make the necessary alterations in the addresses or qualifications of the persons registered under this Act, and to enable the respective Registrars duly to fulfil the duties imposed upon them it shall be lawful for the Registrar to write a letter to any registered person addressed to him according to his address on the Register to inquire whether he has ceased to practise or has changed his residence and if no answer shall be returned to such letter within the period of six months from the sending of the letter it shall be lawful to erase the name of such person from the Register provided always that the same may be restored by the General Council should they think fit to make an order to that effect."

—I am, etc.,

London W 1 Sept 20th

NORMAN C KING,  
Registrar General Medical Council

## MINKERS' NYSTAGMUS AND ULTRA-VIOLET RAYS

SIR,—The note on the sympathetic system in minkers' nystagmus (BRITISH MEDICAL JOURNAL, August 20th, p. 303) induces me to say that I have been treating cases of minkers' nystagmus by general ultra-violet radiation for the last nine months and have found the results most disappointing. I cannot record a single case so treated that has shown any earlier alleviation of symptoms than have those treated merely by rest or light work.—I am, etc.,

G. F. HARCRAFT, M.R.C.S., L.R.C.P.,  
Wolverhampton Aug 23th. D.O.M. and S.

## Obituary

SIDNEY RAWSON WILSON, M.B., M.Sc.,

F.R.C.S.E.D.,

Senior Anaesthetist Royal Infirmary, Manchester, and Lecturer in Applied Physiology and Anaesthetics, University of Manchester

THE tragic death of Mr Sidney R. Wilson last week removes a brilliant son of Owens College and a pioneer in the anaesthetic branch of the medical sciences. Mr Wilson was found dead on September 12th in his study, on his face was a mask, such as is used in the administration of gas and oxygen, and he appears to have met his death while experimenting with this anaesthetic on himself. He retired to his room at 3 o'clock in the afternoon and was not seen again alive. At 5 o'clock he was to have given an anaesthetic at a nursing home, and a telephone mes- senger came to inquire why he had not kept the appointment. His wife found him dead in his room with the mask on his face and a strong smell of nitrous oxide gas in the air. Artificial respiration was performed for some hours, without avail. He was known to be making experiments with the McKesson apparatus to find out the effects of different mixtures of nitrous oxide, oxygen, and air. The actual problem on which he was engaged was whether the anaesthetic properties of various gases and vapours were due to oxygen lack, or were produced by the action upon nerve cells.

Sidney Rawson Wilson was born in 1882 and was the third and youngest son of Dr A. C. J. Wilson of Penistone. His father is still alive and in active practice in the Penistone district. He was a grandson of the late George Wilson of Manchester, the chairman of the Anti Corn Law League, a well known Manchester worthy of his day, of whom a bust and oil painting are to be seen in the Manchester Town Hall. S. R. Wilson was educated at Owens College, and received his hospital training at Manchester, afterwards serving as house-surgeon at the Royal Infirmary. He graduated M.B., B.Ch. with honours at Manchester in 1905, and in the same year obtained the M.B., B.S. degrees of the University of London with honours and distinction. In 1902 he took the B.Sc. degree of Manchester with first class honours. He obtained many medals, scholarships, and exhibitions during the early part of his training, and, as a student, had a most distinguished career. Specializing in anaesthetics he came to be recognized as one of the foremost anaesthetists in the country, and he was a pioneer in many new methods. He was senior anaesthetist to the Manchester Royal Infirmary, and honorary anaesthetist to the Victoria Dental Hospital and Salford Royal Hospital. He held the post of lecturer in applied physiology and anaesthetics at Manchester University and lecturer in anaesthetics at the Dental Hospital.

He contributed numerous articles to the medical journals on the subject in which he was specially interested, and recently read a paper on anaesthetics before the Royal Society of Medicine. In 1922, in collaboration with Mr A. H. Southam, he contributed to the BRITISH MEDICAL JOURNAL a paper on cancer of the scrotum, which was the first published work to draw attention to the occurrence of mule-spinner's cancer among cotton workers. This paper aroused considerable interest, both in medical and lay circles, and resulted in special legislation being undertaken by the Home Office to deal with the disease. More recently he published in the *Lancet* an article on ether convulsions, which he attributed to impurities in the ether used, this paper also evoked much interest and discussion.

A colleague writes: "The death of 'S. R.' as he was commonly known to a very wide circle of friends and colleagues, is a very serious loss to medicine in Manchester, and the news came as a terrible shock to those who had the privilege of his acquaintance. His death will be no less keenly regretted by the students at the University and the Dental Hospital, where his teaching and methods were greatly appreciated by all who came into contact with him. As an anaesthetist it was a pleasure to watch him, and there is never any cause for anxiety when 'S. R.' was in charge of the case. In addition, he was

a born teacher and had a gift of imparting his knowledge such as is given to few. His quiet voice when reassuring patients and thereby gaining their confidence will long be remembered by those who came under his hands. His gentleness and ability when dealing with children was a gift given to few men and was a joy to see. While most of his time was fully occupied with his professional duties he still managed to take an interest in sport. He was a familiar figure at many boxing contests in Manchester and occasionally found time for a round of golf. A friend who spent holidays with him at the seaside noted the great affection he was held in by children wherever "S R" was to be found there was always a circle of young people around him. He is survived by a widow and two children. In a very happy family life his only cause for anxiety was probably for his son, who suffered from diabetes and needed constant and watchful care. The interests and welfare of this boy were one of "S R's" greatest concerns and he was seldom so happy as when talking of his boy and helping him with his animals. The funeral on September 16th was a spontaneous demonstration of the affection and esteem with which he was regarded. The one consolation to his friends is that though he has gone, his work and memory will live after him.

Many of our readers must have seen with regret the announcement of the death in Canada at the age of 53 of Sir WILLIAM CLYDE JONES who was for many years the leading figure in British pharmacy. In his early days he acted as dispenser to a succession of medical practitioners in London and then set up as a dispensing chemist on his own account in the East End. He was intimately concerned with the foundation of the Proprietary Articles Trade Association and was a vigorous member of the council of the Pharmaceutical Society of Great Britain from 1879 to 1904 the year in which he was called to the Bar. In 1903 he was appointed parliamentary secretary to the society and two years later became M.P. for Stepney. In the House of Commons he rendered immense services to pharmacy and pharmacists more particularly in connexion with the National Injunction Acts and the Poisons and Pharmacy Act. During the war he was for a time parliamentary secretary to Dr. Addison and in 1919 he was knighted, shortly after his appointment as secretary of the Pharmaceutical Society. He resigned that post a year and a half ago in order to become chairman of council of the Canadian Proprietary Articles Association throwing himself with characteristic energy and enthusiasm into the organization of that body. He had been chairman of the Association of Insurance Committees in England and Wales and his textbook on *The Law of Food and Pharmacy* published in 1909 is the standard work on that subject. In an appreciation printed in *The Pharmaceutical Journal and Pharmacist* of September 17th the Medical Secretary of the British Medical Association writes of the many opportunities he had of working with Sir William Glynn Jones on behalf of their respective professions and pays a special tribute to his signal services in connexion with the Dangerous Drugs Act and Regulations.

Dr WILLIAM THOMAS EVANS who died in the Cottage Hospital Bromley Kent at the age of 75 was the son of the late Mr Charles Evans F.R.C.S. and was born in Bakewell, Derbyshire in 1855. He received his medical education at Edinburgh and graduated M.B. Ch.B. in 1875. After holding the post of resident surgeon to the Edinburgh Royal Infirmary he commenced practice in Piddington holding the appointments of medical officer to the west district of this borough and to the St. John's Training School for Civil Worksman Park. He was a member of the British Medical Association and the Royal Medical Society Edinburgh and of the Hygienic Society London. He retired from practice in 1920 and settled in Kent. He is survived by his widow and three children one of whom is Major Douglas Gordon Evans, R.A.M.C.

The following well known foreign medical men have recently died. Dr LOUIS DUMETIL-CHAMBERLON of Tours, president of the Societe d'Anthropologie de Paris, an eminent medical historian and lecturer in the medical school at Tours, and Dr F. W. TILLOTSON, professor of internal medicine at Helsingfors, aged 56.

## Medico-Legal

### A SURGEON'S FEE

An action for the recovery of a fee for performing a surgical operation was heard by His Honour Judge Higgins at Exeter county court on September 13th. The plaintiff was Mr P. A. Worthington F.R.C.S. surgeon in charge of the throat, nose and ear department, Royal Devon and Exeter Hospital and the defendant was Mr S. T. Pitt, Yelverton the claim being for £70 7s being 6 guineas for an operation on defendant's daughter and 7 guineas as a retainer's charge.

Mr J. L. Pratt for the plaintiff said the operation was performed on defendant's daughter aged 15 at a time when he was in the Exeter Infirmary Hospital. The daughter was a boarder at the Marlborough School. It was discovered that she was suffering from scarlet fever. She had her own medical attendant at the school but as it was a case of scarlet fever arrangements were made for her to go to the Infirmary Hospital and at the parents' request she was put in a special ward. At the end of a month (January 24th) the scarlet fever was cured and Dr Strick the medical officer, would have been willing that she should leave hospital but it was found that the girl was suffering from a discharge from the ear and that an operation would probably be necessary. In fact the girl would have died if an operation had not taken place. The matron of the hospital advised Mr Pitt about this and pointed out that in Dr Strick's view it was a case in which a special fee was needed. Counsel said defendant could have been under no misapprehension that he would be liable for the fee because the usual notice as to this was sent to him.

Dr P. H. Strick, city medical officer who is in charge of the Infirmary Hospital testified that defendant was present at a consultation on January 24th when Mr Worthington expressed the opinion that an operation was necessary. The local authority did not pay specialists' fees.

Mr Worthington in his evidence said that at the consultation both Mr and Mrs Pitt were present. Witness advised an operation. Defendant did not consent then but two hours later witness received a telephone message from Mr Pitt authorizing him to go on with the operation. Witness found the condition of the child so serious that it was fortunate she was operated on. As to the fee he usual charge for such a case was 100 guineas but in this case he made a reduction.

Defendant's counsel sought to say Dr Worthington that his daughter has died still and was dead before the operation was done.

The matron and a nurse at the Infirmary Hospital spoke to conversation defendant's wife had with them as to what Dr Worthington's fee would be.

Defendant said he had no evidence to offer beyond that already given by the documents.

His Honour said it seems to him defendant was liable and there would be judgment for the amount claimed. The defendant expressed his intention to appeal on a point of law.

## Universities and Colleges

### UNIVERSITY OF DUBLIN

Mr DONALD B. GRIFFIN M.D. F.R.C.S. who has been lecturer on anatomy in the University of Durham College of Medicine Newcastle-on-Tyne for the past five years has been elected to the Chair of Anatomy in succession to Prof. Dr P. H. Warden whose resignation was recently announced.

### UNIVERSITY OF LEEDS

On the occasion of the visit of the British Association to Leeds the honorary degree of Doctor of Laws was conferred by the University upon the President Sir Arthur Keith M.D. F.R.S. and that of Doctor of Science upon Prof. Dr J. S. Haldane M.D. F.R.S.

## The Services

### HONORARY PHYSICIAN TO THE KING

HIS MAJESTY has approved of the appointment of Lieut. Colonel C. P. Chittenden C.I.E. OFF. MB. Indian Medical Service as Honorary Physician to His Majesty the King with effect from February 15th 1927 in succession to Lieut. Colonel C. E. Denham C.I.E. Indian Medical Service who has retired.

### HONORARY SURGEON TO THE KING

HIS MAJESTY has approved of the appointment of Major-General G. Tate M.D. Indian Medical Service as Honorary Surgeon to the King with effect from February 27th 1927 in succession to Major-General P. Heard C.I.E. Indian Medical Service who has retired.

## Medical News.

THE annual prize distribution at St George's Hospital Medical School will be held in the board room of the hospital on Saturday, October 1st, at 3 p.m., when the inaugural address, entitled "The meaning and methods of success," will be delivered by Sir Humphry Rolleston, Bt, KCB, MD, Regius Professor of Physic in the University of Cambridge. The annual dinner of the medical school will be held at the Hyde Park Hotel on Saturday, October 1st, at 7.15 for 7.45 p.m., with Sir Humphry Rolleston in the chair.

THE opening of the winter session at the London (Royal Free Hospital) School of Medicine for Women will be held on Monday, October 3rd, at 3.30 p.m. The introductory address will be given by Mr Robert G Hogarth, CBE, FRCS, senior surgeon, General Hospital, Nottingham, whose subject will be "The doctor's high calling." Academic dress will be worn.

THE opening ceremony of the winter session at King's College Hospital Medical School will be held on Friday, September 30th, at 2.30 p.m. The introductory address will be given by Sir Berkeley Moynihan, Bt, President of the Royal College of Surgeons of England. The annual dinner of past and present students will be held at 7 for 7.30 on the same day at the Criterion Restaurant, Piccadilly Circus, when the chair will be taken by Professor G F Still, MD.

THE annual distribution of prizes at Charing Cross Hospital Medical School will take place in the outpatients' hall of the hospital on Wednesday, October 5th, at 3.30 p.m. The annual dinner of past and present students will be held at the Hotel Victoria, Northumberland Avenue, on the same evening, at 7 for 7.30 p.m., when the chair will be taken by Dr Cuthbert Lockyer.

THE winter session at the Royal Veterinary College, Great College Street, Camden Town, will begin on Tuesday, October 4th, when the opening address will be given at 3 p.m.

THE eighty-sixth session of the School of Pharmacy of the Pharmaceutical Society of Great Britain will open on Wednesday, October 5th. The inaugural sessional address will be given by Dr T A Henry, at 3 p.m., in the Society's house, 17, Bloomsbury Square.

THE Fellowship of Medicine announces that a course in cardiology will be held at the National Hospital for Diseases of the Heart from October 3rd to 15th, from 10 a.m. to 4 p.m. each day (limited to 20). The Central London Throat, Nose, and Ear Hospital will hold a three-week course from October 3rd to 22nd, the clinical and operative parts of the course may be taken separately or together. There will also be practical courses in peritoneal endoscopy, and in bacteriology and pathology suitable for DLO students. Other courses in October will include ante-natal work at the Royal Free Hospital, at 5 p.m., on Fridays, October 7th to 28th (membership limited to 10), in diseases of children at the Paddington Green and the Victoria Children's Hospital, morning and afternoon alternately at each hospital, from October 17th to 23th, in electrotherapy at the Royal Free Hospital, on Wednesday, at 5.15 p.m., from October 12th to November 2nd, in gynaecology at the Chelsea Hospital, from October 17th to 29th, in tropical medicine at the London School of Tropical Medicine, Tuesdays and Thursdays, at 2 p.m. from October 4th to 27th, and in neurology at the National Hospital, Queen Square, from October 3rd to November 25th. Copies of syllabuses and of the general course programme are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W1.

A WEEK END post graduate course at St Mary's Hospital, Paddington, has been arranged. On October 1st Professor C A Faunett will deal with minor operative problems of general practice, Sir William Wilcox, the treatment of pernicious anaemia, Dr T G Stevens, Caesarean section and after, and Mr Zachary Cope, retention of urine in an old man. On October 2nd Dr Ernest Young will discuss the duodenal tube in treatment of gastric and duodenal ulcers, Dr C M Wilson, early recognition of some common diseases, and Dr John Freeman, blood transfusion. On October 3rd Dr Wilfred Harris will deal with the significance of pain in the lower extremities, Mr S Maynard Smith with obstruction of the large bowel, and lantern lectures will be given by Mr Alec W Bonine on recent work on the pituitary and ovary, and Mr Duvern Fitzwilliams on early diagnosis of carcinoma of the tongue. The meetings are open to all medical practitioners without fee.

A SHORT course of lectures on functional nervous disorders will be given at the Lystock Square Clinic for Functional Nervous Disorders, 51, Lystock Square, London, WC1, commencing on October 10th. The fee for the course to

medical practitioners is £2.2s and to medical students 10s 6d. Tickets and full particulars of the course can be obtained in advance from the honorary secretary of the clinic.

AN international congress of hygiene will be held in Paris under the presidency of Professor Leon Bernard from October 25th to 28th, when the following questions will be discussed: Relation of insurance to public health, introduced by Kuhn of Copenhagen, Holtzmann of Strasbourg, and Brian of Paris, factors in the recrudescence of small pox and the means of combating them, introduced by Ricardo Jorge of Lisbon, Jitta of the Hague, and Camus of Paris, hygiene of education camps, introduced by Siquezee of Paris. Addresses will also be delivered by Professors Madsen and Ottolenghi. The subscription of 60 francs should be sent to the general secretary, Dr Dujaire de la Riviere, Institut Pasteur, Rue Dutot 25, Paris XV.

THE P L M Railway informs us that the through service from London to the Riviera will this winter run in connexion with the 2 o'clock boat train from Victoria via Folkestone Boulogne instead of the 11 o'clock via Dover Calais as hitherto. The arrival at Riviera destinations will, however, be only approximately a quarter of an hour later, thus shortening the total journey by two and three quarter hours. The new service will run for the first time on October 25th next, and will provide the usual sleeping accommodation and also ordinary 1st and 2nd class seats.

DR JOHN BEATTIE, research assistant and demonstrator of anatomy at University College, London, has been appointed assistant professor of anatomy at McGill College, Montreal.

A CONSIDERABLE epidemic of infantile paralysis is reported from Alberta. Fresh cases have been recorded daily, and the reopening of the schools has been postponed by the Board of Health. According to the Toronto correspondent of the *Times*, the medical authorities of Edmonton, the capital of the province, have appealed to the Rockefeller Foundation for assistance in combating the epidemic, and have asked that a representative may be sent to study the local situation.

A STATUTORY order issued by the Home Office will come into force on October 1st, requiring the provision of an adequate supply of water for washing and drinking purposes in factories and workshops in which gutting, salting, and packing of herrings are carried on. A first aid dressing station must be established within 250 yards of the factory or workshop, and be in the charge of a qualified nurse or other person trained in first aid.

THE sixth Roumanian Congress of Oto-rhino-laryngology will be held at Bucharest on October 29th and 30th, under the presidency of Professor Piedescu Riou of Cluj. Papers will be read on foreign bodies in the trachea, bronchi, and oesophagus, by Professor Belmoff of Sofia and Dr Potirade, and on syphilis of the ear by Drs Tempea and Costina, jun. Further information can be obtained from the general secretary, Dr L. Mayersohn, 81, Calea Musilor, Bucharest.

THE annual statutory general meeting of the Medical Defence Union Ltd, will be held at the Royal Bath Hospital, Harrogate, to-day (Saturday, September 24th), at 4.30 p.m.

THE annual dinner of the West Kent Medico-Chirurgical Society will be held on Wednesday, October 12th, at 7.30 p.m., at the Piccadillo Restaurant, Piccadilly Circus. Tickets 10s 6d each, exclusive of wines, may be obtained from Dr J P Purvis, 16, The Grove, Greenwich, SE 10. Ladies are invited.

THE third annual Norman Lockyer Lecture before the British Science Guild will be given by the Very Rev. Dean Inge on the afternoon of Monday, November 21st, in the Goldsmiths' Hall. Particulars will be announced later.

THE Jewish Health Organization of Great Britain is a body which has the support of a large number of well known Jewish medical men. It appears also to be a very active body, and, although the annual report just issued is only the third, it possesses already some nine different committees. It promotes health education by means of lectures and publications, it is establishing an annual Health Sabbath in connexion with the Health Week of the Royal Sanitary Institute, and it is opening a clinic for nervous and difficult children. It is also engaged in inquiries into the types of visual defect and the prevalence of left handedness in Jewish children, the mortality from cancer amongst Jews, and the comparative intelligence and attainments of Jewish and non Jewish school children.

THE centenary of the birth of Villemin (1827-92), medical inspector of the French army and professor at the Val de Grace School of Medicine, who discovered the virulence, specificity, and contagiousness of tuberculosis in 1865 will be celebrated at Paris, under the patronage of the President of the Republic, from October 15th to 18th, immediately after the French Congress of Medicine.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House Tavistock Square W.C.1**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **British Medical Journal** must communicate with the Financial Secretary and Business Manager, British Medical Association House Tavistock Square W.C.1 on receipt of proofs.

All communications with reference to **ADVERTISEMENTS** as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **British Medical Journal** are **MUSEUM 9561 9562 9563** and **677** (internal exchange four lines).

The **TELEGRAPHIC ADDRESSES** are

**EDITOR OF THE BRITISH MEDICAL JOURNAL, Articology Westcent London**

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements etc.) **Articology Westcent London**

**MEDICAL SECRETARY Medicine Westcent London**

The address of the Irish Office of the British Medical Association is 16 South Frederick Street Dublin (telegrams **Naclius Dublin** telephone 4737 Dublin) and of the Scottish Office 5 Drumstrath Gardens Edinburgh (telegrams **Associate Edinburgh** telephone 4581 Central).

### QUERIES AND ANSWERS

#### UPINE STAINS

**INCONTINENCE** writes: A patient is suffering from precipitancy and frequency of micturition with slight dribbling after micturition dating from the passage of a cystoscope several years ago used for diagnostic purposes after a prolonged attack of renal haemorrhage the cause of which was not determined. He is greatly troubled by the consequent staining of his shirts and trousers when these are of light coloured material and would be very grateful for information of any application which would remove this staining. Ordinary dry cleaning and the application of benzol petrol and turpentine have been tried without much effect.

#### BORING THE LOBULE

**K.W.** writes: Two of my women patients insist on my boring their ears for wearing rings and I should like a few hints as to technique.

We have always looked on this procedure not as a surgical operation but as the removal of a barbaric mutilation, general some years ago but now becoming rare and usually performed by jewellers. The method as described to us long ago was as follows: The lobule of the ear was pressed against a piece of cork, the eyes of the patient were shut tight and a coarse needle was stabbed through the lobule into the cork, an open link of gold chain was then pushed through the perforation and suitable restoratives were administered. We suggest to our correspondent that in order to signify the importance of the rite he should pass a small trocar and cannula through the lobule after due aseptic and antiseptic precautions, withdraw the trocar and follow it out with a piece of silver or gold wire, withdraw the cannula leaving the wire in the lobule and then bend the wire into a ring.

#### INCOME TAX

**WEST AFRICA** inquires what tax would be payable on an income of £1900 (£875 earned) in his circumstances, he has three children the eldest of whom is under 15 and in receipt of a scholarship of £150 per annum.

The duty is as follows

		£140	£1000
		20	
			51
Taxable income	£1900		51
Tax due at 2 in the £ on £225		5 22 10	
do at 2 in the £ on £121		2 16 0	
Total tax payable		£25 6 0	

If West Africa is a widower the personal allowance is £135 and the tax payable will be increased by £13.

### DIAPHORETICS AND DIURETICS

**DR. T. G. GARDNER** (Oxford) writes in reply to **Scrutator** (JOURNAL September 10th 1927 p. 476) who asked for suggestions for making diaphoretic and diuretic mixtures palatable: "A chloroform as a vehicle will answer his purpose." "I am in my opinion" "it certainly is more pleasant—just as food is more likely to agree" when it is presented in a dainty form.

### LETTERS, NOTES, ETC.

#### TWO MEDICAL SAINTS

**DR. BASIL H. PAIN** (Southborough, Tisbury Wells) writes: While on holiday in Kent this year I found myself in the little parish church of St Cosmo and St Damian in the Bleau to give it its full name but called locally Blean. It is situated about three miles north of Canterbury. The names of the two saints are rare in English churches. A full account of their lives and doings appears in Young's *Annals of the Barber Surgeon*. There we learn that they are the patron saints of the barber surgeons that they were Ambrosius by birth but dwelt in Aegae a city of Cilicia. They practised medicine and surgery but took no fees in payment. Naturally they were in high esteem. On the title page of the old Book of Ordinances of the Barber Surgeons they are represented as supporters of the coat of arms of the barber surgeons. One of the saints holds a medical vessel in his right hand while the other saint has a box of ointment and a sprig indicative of their being professors of the healing art. The vicar of Ilean told me that there were only two churches in the United Kingdom dedicated to these saints and both were in Kent. He then showed me a stained glass window in the church St Cosmo (or Cosmas) is shown holding in his left hand a goodly box of pills with the lid removed and between the thumb and first finger of his right hand lies a well shaped pill. St Damian is shown holding a pestle and mortar. They were martyred in Cilicia in the Diocletian persecution in 303 A.D. The vicar also told me that he had returned from Greece and that there were at least fifty chapels dedicated to these saints within a few miles of Athens. I read 'they ministered to all who applied to them whether rich or poor so they deserve to be kept in memory by the medical profession. Their Commemorative Day I see happens to be September 27th.

The names of the two saints with that of the Beloved Physician are commemorated in the title of the Guild of St Luke, St Cosmas and St Damian a Roman Catholic body with headquarters in London and a considerable medical membership.

#### TREATMENT OF WHITLOW BY X RAYS

**DR. A. A. MASSER** (Penistone, Sheffield) writes to report the rapid recovery of a whitlow on his right thumb after exposure to x rays. He states that about three months ago he contracted a deep thecal whitlow which also involved the terminal phalanx. A deep incision was made but the thumb continued to discharge from two sinuses for nearly a fortnight and no radiograph was taken. Almost immediately after exposure to the x rays the pain in the thumb vanished and by the following morning all discharge had ceased the sinuses closing within twenty-four hours. The x ray examination revealed necrosis of the tip of the phalanx. The thumb is now quite normal except for a slight scar caused by the incision. Dr. Masser has been unable to find any reference in the literature to the therapeutic action of x rays in septic or inflammatory conditions and in view of his own experience he suggests that small doses might be tried in the hope of accelerating the recovery of infected wounds.

#### EFFECT OF PARIS GREEN ON MOSQUITO LARVAE

**DR. PADMANABHA MENON** of the Ross Institute London has published in the issue of the *Journal of Tropical Medicine and Hygiene* for August 1st a short account of the effect of Paris green on culicine larvae—the report of some experimental work. He found that Paris green vigorously shaken with water suks and the granules are eaten by mosquito larvae which subsequently die though in the very early stage of development they seem to escape. Paris green was not found to be toxic to mosquito pupae.

#### THE UNMARRIED MOTHER AND HER CHILD

The ninth annual report Mother and Her Child in the Leithmar Act of 1900 is legitimized by the subsequent marriage of its parents in each other provided certain conditions are observed. Similar notices did not attend the Bastardy Bill introduced into the House of Lords. The bill has now been modified in respect to the hearing of affidavits in cases before the birth of the child, the payment by the father towards the support of the mother during the later months of pregnancy and for commencement expenses, and the power to secure an affidavit in order to be given to guardians or board of guardians in the event of insanity or death of the mother. An attempt will be made to introduce the modified bill in the House of Commons.

## RELUCPENT EPISTAXIS

Dr W NUNAN (police surgeon, Bombay), having noticed several inquiries about the treatment of recurrent epistaxis, writes to suggest it is out to mental suggestion. "Anyone," he says, "who has had opportunities of observing the results of suggestion in cases of spasmodic dysmenorrhoea and menorrhagia, crinices, and pylorospasm will have no difficulty in appreciating the value of suggestion therapy in the control of contractions of unstriated muscle fibres."

## "SUBINVOLUTION PERITONITIS" (?)

Dr DOUGLAS A MITCHELL (Bath) writes. The histionic genius of the vermiform appendix is so generally recognized nowadays that it is apt to be blamed for the large majority of lower abdominal infections where no other gross lesion is demonstrable. In recent years I have seen several cases of acute abdominal crises in women necessitating operation, in which the greatest elasticity of imagination was necessary to incriminate the appendix, but in which the following triad of conditions was present: (1) A heavy, bulky uterus, with the typical "doughy" consistency of "subinvolution," and covered with comparatively listless and almost diabolically coloured peritoneum, (2) intensely red and congested, but not distended, tubes, (3) a quantity of clear or slightly sanguinous fluid in the pelvis, with hyperemic reaction in the adjacent coils of small intestine. In the last two cases of this condition of which I have notes there was an interval of four months since the last (straightforward) confinement. In such cases, though the history and symptoms may give a perfect picture of fulminating appendicitis, no pathological changes are found in the appendix. If this condition is truly one of "subinvolution peritonitis," due to the direct transmission of organisms, or even toxic material, from the uterus along the tubes to the peritoneal cavity, and if the condition is at all common, it must enhance the importance of subinvolution considerably. It would be interesting to have the opinions of surgeons and gynaecologists.

## NORMAL LABOUR AFTER CAESAREAN SECTION

Dr J L BLONSTERN (London, S.W.) writes. A woman, aged 22, had undergone Caesarean section two years ago on account of active tuberculosis of the hip joint, when a five months foetus was removed. It was her first pregnancy. She came to see me when she was eight months pregnant. She stated that three hospitals had refused to admit her, unless she again submitted to Caesarean section. I found no pelvic contraction, no signs of hip joint disease, and I decided to let her go to term. The child was in a vertex position. When labour started she had weak pains at long intervals for seven days. For two days she had strong pains at frequent intervals, but there was little progress. When I found the os dilating I gave a hypodermic injection of half a grain of morphine. She slept for an hour, and then I was sent for. Before my arrival the child and placenta were born. There was only one small tear. The child was healthy and weighed 8 lb. The puerperium was uneventful. I think this case illustrates the fact that, providing the pelvic measurements are normal and progress is carefully watched, there is no reason why a woman who has previously undergone Caesarean section should not be delivered normally.

## CARDIAC RUPTURE

Dr R B WILSON (Glengall Hospital, Ayr) writes to record the death of a woman, aged 63, from cardiac rupture. She had been in poor physical health for some months and was found dead in bed one morning. At the necropsy blood clot was discovered in the pericardium, and there was a rent 3/4 in long in the left ventricle. Further, localized weakness of the fatigued degenerated heart muscle had resulted apparently from a deep eroding ulcer, which was probably gummatous. The patient had been asleep, without any signs of distress, fifteen minutes before death, and there was no history of any undue exertion, recent or remote.

## A STAIN FOR SPERMATOZOEA

Dr S MALIHANAH (Hyderabad, Deccan) has found the following method of detecting spermatozoa in seminal stains an improvement on that of Hankin, which is commonly used in India. He cuts off a piece of cloth from the garments showing any suspicious stains of semen and places it in a sterile petri dish containing a solution just enough to soak it. After labelling, the petri dish with the number of the case and the date, it is set aside for a few minutes. With a clean knife the film is scraped gently from the cloth on to a clean slide and spread gently. It is allowed to dry in air and then fixed with the flame of a spirit lamp and covered with a few drops of carbolfuchsin. After a few minutes it is washed with distilled water and dried by being kept slanting so that the water drains away. The portion of the spermatozoon which lies between the head and the tail takes the stain more deeply and is generally semicircular in shape. The horns of this semicircular body have a tendency to unite in front and the coloration elsewhere is generally very faint. This peculiar staining characterizes the spermatozoon, which can be easily distinguished from cells and bacteria. The staining is more intense towards the tail and less towards the front part of the head. In fresh preparations, however, the tail also becomes coloured, but in actual practice, when the specimens are old, the tails do not take up the stain. Dr Malihanah adds that by this method he has obtained positive results in 85 to 90 per cent of cases, in most of which two or three males had been present.

## PREVENTION OF GOITRE

"S O" writes. The prevention of goitre is a matter of great importance to those who live in goitrous districts. Colloidal iodine and iodized sweets have been used successfully to treat goitre and many other conditions. Since iodized salt contains so small a quantity of iodine as to be useless, I venture to ask, if any reader would suggest a simple, practical method of preventing the onset of goitre and of these diseases which are said to be due to deficiency of iodine. "Irish moss" is certainly useful in the treatment of goitre, but I have not used it for a sufficient length of time to satisfy myself that it will prevent goitre. It would be interesting to know if Sir James Barr (whose letter on this subject appears in the JOURNAL of September 10th, p. 470) still uses concussion of the spinous process of the seventh cervical vertebra in the treatment of thyroid enlargement.

## DEFINITION OF INSANITY

Dr F H STEGMANN (Kingston, South Australia) writes with reference to the remarks on the absence of any definition of insanity made by Mr Justice McCardie, as reported in the JOURNAL of June 4th, 1927 (p. 1038), to say that Dr James H. Macdonald, of the Hawkshead Mental Hospital, Glasgow, gave the following definition. Insanity is a more or less permanent disease or derangement of the brain producing disordered action of the mind in such a way as to put the subject into a condition varying from his normal self and out of relation with his environment, and at the same time to render him dangerous or inconvenient to himself or his fellow men. Dr Stegmann thinks that by adopting a definition such as this medical men would save themselves from adverse cross examination tending to discredit a case.

## THE CUBAN LEAGUE AGAINST CANCER

CUBA is following the example of other countries in making efforts to reduce the mortality from cancer. It has its anti-cancer league undertaking to collect and distribute information relating to cancer, to promote the study of the disease, and to educate the poorer population in the knowledge of what science can do in the way of alleviation and cure, and recently it has given an earnest of its determination to show definite results from its mission by the gratuitous distribution to all the practitioners in the Republic of a volume of over 150 pages dealing with the important subject of early diagnosis. The book contains descriptions of the disease as it affects the principal regions of the body and is written by specialists. As it is designed for the benefit and instruction of practitioners, they are addressed with it. It is, in fact, a primer, to realize the particular is customary in other countries. In countries the practitioner is reluctant, though good nature, to hurt the feelings of his patients by making a diagnosis of cancer. This may not be the case in Cuba, but there appears to be a species of religious superstition in the island that cancer is an incurable disease. Dr Tamarro lays emphasis on the responsibility resting on the medical practitioner. He declares that the doctor who is jealous of his professional prestige must devote serious consideration to the opinion he gives, since it is better frankly to confess inexperience than to be compelled to rectify a diagnosis when perhaps it is too late. He should remember that a patient who is told that he is suffering merely from a non-malignant growth will expect a rapid cure, and if this does not follow the treatment recommended, other advice will be sought, and should there have been an error of diagnosis or an attempt to deceive this fact will not remain a secret. No less reprehensible is a rash and ill-considered resort to intervention in the form of an incomplete operation or the employment of caustics and other local applications. If a case is operable and the practitioner has not the personal equipment for performing a radical operation he should send the patient to those possessing the necessary experience or to a hospital. The volume is evidently designed to impress the practitioner with the necessity of ascertaining how far extent cancer is curable in these days, and of learning how to recognize it in the early stages instead of dallying with it in ignorance until the patient's condition has become hopeless.

## TRIATUM

IN the preliminary note on the proceedings of the Section of Mental Diseases at the Annual Meeting at Edinburgh (July 30th, p. 165 col. 2) it is stated that "Dr Groves described a case of recurrent mental illness in a girl." The speaker was not Dr Groves, but Dr T. C. Groves, medical superintendent of Rubery Hill and Hollowmoor Mental Hospitals, Birmingham.

## VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 37, 38, 39, 42, and 43 of our advertisement columns and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 135.

## THE FUTURE RELATION OF MUNICIPALITIES TO VOLUNTARY HOSPITALS

### I—THE QUESTION OF CO-OPERATION BETWEEN VOLUNTARY AND MUNICIPAL HOSPITALS

BY

HERBERT L. EASON, C.B. CMG, M.D. M.S.

Senior Ophthalmic Surgeon and Superintendent, Guy's Hospital

At the outset I want to say that, much as I appreciate the compliment of being asked to open this discussion, I feel entirely incompetent to do so. The field to be covered is so vast and so varied that I doubt if any one person can cover it satisfactorily. I have moreover no confidence in my capacities as a prophet. Prophecies are always hazardous ventures so that I feel that the best I can do this morning is to express my own personal views on present conditions, and on what I hope may happen in the future. I am going still further to limit myself, and to confine myself to that part of the field with which I may to some extent be familiar—namely, the problem as it affects voluntary hospitals in London with medical schools. I do this with the hope that other speakers may attack the questions from the point of view of other institutions and other localities.

Before discussing the future, it may be as well briefly to recapitulate the existing relationship between the voluntary hospital and State and municipal institutions. Some of these relationships are official and some of them are merely matters of custom, habit and tradition.

The State itself has little relationship to the voluntary hospitals except in so far as it may control ante-natal or infant welfare centres, or may come in contact with the hospitals through their medical schools which may receive a grant from the Treasury Grants Committee. In these circumstances the representatives of the University Grants Committee or of the Minister of Health have a right of access to the hospital in order to satisfy themselves that the arrangements for the instruction of students are adequate, both from the point of view of ward and laboratory accommodation and of educational facilities.

The relationship of the voluntary hospitals to the municipality—the London County Council—is in many hospitals more intimate, particularly where the municipality finances such departments as venereal diseases departments and school clinics. A venereal diseases department is administered by the voluntary hospital which appoints the staff, arranges for the equipment of the department, and is responsible for its conduct subject to the approval of the London County Council. The County Council inspects the department from time to time and the voluntary hospital, at the end of the year presents the bill to the County Council in the form of a report and a financial statement. The County Council then makes a grant to cover if not the whole the greater part of the expense of the department.

The relationship of the voluntary hospitals to the Metropolitan Asylums Board is laid down by law—that is, certain infectious diseases must be notified to the public health authorities and the Metropolitan Asylums Board hospitals must admit such cases from the voluntary hospitals if notified.

The relationship of the Poor Law infirmaries which are in a sense municipal, though they are not as yet under the control of the chief municipal authority—and the voluntary hospitals is fairly simple. The voluntary hospitals are accustomed to transfer to the appropriate infirmary any case which in the opinion of its medical officers requires institutional treatment but for which there is no room in the voluntary hospital. The Poor Law infirmary must admit a patient so recommended, either through the relieving officer or directly to the

infirmary in accordance with local arrangements as between the hospital and the infirmary.

But well above these comparatively simple functions there has of recent years been a great development in the activities both of municipal and Metropolitan Asylums Board institutions in the direction of treating special classes or special conditions in particular institutions, thus impinging on the province of the general hospitals, and these developments are not without danger to the effective education of medical students in the schools attached to voluntary hospitals.

In this connexion I cannot do better than quote from an able leading article in the *BRITISH MEDICAL JOURNAL* of June 11th, 1927 (p. 1054).

At its meeting in April the Council of the British Medical Association approving a report with regard to orthopaedic clinics, pointed out that one of the dangers attending the establishment of such clinics is the withdrawal of a large number of cases of a special type from those hospitals in which medical education is carried on in connexion with medical schools, so adding to the difficulties of securing an adequate knowledge of such conditions among medical practitioners in general.

The anxiety is by no means premature. There are now no fewer than seventeen departments, spheres or directions of clinical activity for which provision is made in this sectional way under the auspices of local authorities. Some of these cover an extensive field of medicine and in some there has arisen the obvious and increasingly insistent suggestion that the public needs can be better met by authorization, the placing of responsibility for giving advice and treatment upon persons other than qualified and registered medical practitioners. For in a sense we have heard it claimed that midwives are quite capable of dealing with ante-natal conditions that school nurses under the purely nominal supervision of a medical officer may safely be left to treat what are called the minor ailments of school children and that dentists rather than medical practitioners should be entrusted with the administration of certain classes of anaesthetics. The pretensions of some opticians, now being pressed with a good deal of parliamentary sympathy are especially dangerous. They are a king that the State should officially recognize them and register them as being the most skilled if not the only legitimate practitioners in an extensive field of ophthalmic treatment and that their certificates within this field shall be under authority compulsory recognized by any local or central authority or Government department in any part of Great Britain.

Two interlocked vicious circles are in fact being established. There is danger that medical students may be imperfectly instructed in some part of their work owing to the withdrawal of special types of case to the clinics of local authorities and there is danger that it may become difficult properly to staff those clinics owing to imperfect training of medical students. There is danger that unqualified persons may be officially recognized in certain fields of medical work owing to alleged insufficiency in the supply of competent medical practitioners and there is danger that a progressively smaller number of qualified medical practitioners will cultivate those fields owing to their remunerative clientele being seriously diminished by the official recognition of the unqualified person. If Parliament and the Government department concerned the local authorities and the powers within the medical profession are wise however it is not yet too late to avoid these dangers.

This is neither the time nor the place to pursue all the ultimate implications of this statement but it is sufficient here to emphasize that, in all discussions as to the future, we must, in the interests both of medical education and of the public, insist that no arrangements will be approved which will destroy or interfere with the free access of all types of disease whether serious or trivial, to the voluntary hospitals with medical schools.

As an illustration of developments alluded to in the *BRITISH MEDICAL JOURNAL* I set out below some but possibly not all, of the sectional departments in which provision is now made for separate types of disease.

Small pox	M.A.B. (Metropolitan Asylums Board)
Other notifiable infectious diseases	M.A.B.
Venereal disease	L.C.C. (London County Council)
Tuberculosis	L.C.C. and M.A.P.
Ante-natal work	Municipal or Health
Maternity and puerperal pyrexia	Boards of Guardians
Infirmaries	Ministry of Health
Minor ailments of school children and babies	
Refraction and other ophthalmic work	Approved Societies and L.C.C. School Clinics
Tonsil and adenoid	Public Dental Service and L.C.C.
Anaesthetics for dental and adenoid work	
Special cases of ear disease	M.A.B.
Ringworm and treatment	L.C.C. and M.A.P. Goldsmiths' and Leigh Home, Abberley Wood.

A paper opening a discussion in the Section of Medical Sociology at the Annual Meeting of the British Medical Association at Edinburgh. The President of the Section Dr F. A. MacManus was in the chair.

Orthopaedic cases	M A B Queen Mary's Hos pital, Cusshilton
Rheumatic heart disease and choera	M A B Queen Mary's Hos pital, Cusshilton
Mental deficiency	L C C and M A B
Insanity	L C C
Ophthalmia	White Oak School, Swanley, M A B
Ophthalmia neonatorum	M A B St Margaret's Hos pital
Parturient women suffering from venereal disease	Sheffield Street Hospital, Kingsway M A B
Marasmus	Thames Inn Infirmary, M A B M A B St Margaret's Hos pital
Zybotic enteritis	M A B St Margaret's Hos pital

With this very brief summary of the existing relationship of State and municipal hospitals to the voluntary hospitals, I may proceed to the further consideration. Why is it necessary now to discuss their future relationship, and why has the question so suddenly developed such a high importance?

I think the answer to that question lies in the intention of Mr. Neville Chamberlain, the Minister of Health, to bring before Parliament later in this year some proposals for a measure of Poor Law reform.

Mr. Chamberlain's proposals are set out in a memorandum entitled "Provisional Proposals for Poor Law Reform prepared in the Ministry of Health for circulation to the London County Council, Associations of Local Authorities, and others concerned as a basis for consideration and discussion." The objects which Mr. Chamberlain seeks to attain are briefly (and apart from the reduction in the number of local elections and local administrative bodies)

1 The co-ordination and improvement of the provision made for the prevention and treatment of ill health, both institutionally and otherwise, and the inclusion in this provision of all public assistance required as the result of sickness, accident, and infirmity.

In county boroughs a complete unification of the health services can be secured, and as regards administrative counties there is contemplated a concentration in the county council of a general responsibility for the administration of health services in the hands of borough and district councils acting within the county.

2 The co-ordination of all forms of public assistance, and especially an improved correlation between Poor Law relief and unemployment benefit.

3 The decentralization of the responsibility at present falling on the Minister.

4 The simplification of the financial relations between the Ministry and the local authorities and the freeing of the local authorities from the financial restrictions in matters of compulsory detail which are a necessary concomitant of the present system.

5 The correction of certain anomalies of historic origin such as the association of the registration service (births, deaths, and marriages) with the provision for the relief of the poor.

In brief, as principally affecting hospitals, Mr. Chamberlain proposes to take the Poor Law infirmaries out of the hands of the boards of guardians and to put them under the control of the local municipal authority—in the case of London, the London County Council.

Those of us who are interested in the co-ordination and the improvement of the provision made for the prevention and treatment of ill health, both institutionally and otherwise, cannot but feel that the administration of the Poor Law infirmaries by the local municipal authority would be a reform productive of the greatest benefit to the sick, nevertheless, I should like to state at once that I entirely agree with Mr. Neville Chamberlain that these proposals must not be taken to reflect in the slightest degree on the manner in which the boards of guardians have generally carried out their duties in regard to infirmaries.

Nothing has been more striking in recent years than the steady and marked improvement of the standard of professional service both medical and surgical, provided in Poor Law institutions. Within a comparatively recent period they have risen from the position of little more than workhouse infirmaries for the destitute and incurable to that of hospitals differing little from the big voluntary hospitals. The present administration of infirmaries by the Poor Law guardians suffers, however, from two grave defects. The first is the stigma of pauperism. It is a

matter of common and constant experience that patients have the gravest objection either to being sent to the infirmary direct or to being transferred from a voluntary hospital to the infirmary. It is useless to point out to these persons that the medical service provided in these infirmaries is adequate and efficient, there still exists in their minds a deep-rooted antipathy, probably historic in origin, to the infirmary. The infirmary still appears to so many something like the workhouse, in which patients may not be treated with the same kindness and sympathy that they are in a voluntary hospital, and in addition there is that terrible stigma of pauperism. This is a matter of grave moment to patients, both as regards their own self-respect and their standing with their neighbours. The prejudice is inveterate and it is hopeless to argue with many of them. They would sooner take their children or relatives home, however inadequate the accommodation, than let them go to the infirmary, however good it may be, and however kind and efficient is the treatment that they may, and now do, receive in these institutions.

The second defect is that at the present time infirmaries are, and must be, worked in watertight compartments, and hence difficulties and problems are always arising as between voluntary hospitals and infirmaries with regard to the admission of patients. A hospital can only send a patient to the infirmary of the parish in which the patient resides, even though that particular infirmary may be much further away than an infirmary of an adjoining parish. Hence officials and medical officers of hospitals have always to keep in mind the actual road boundaries of the boroughs, and must carefully verify the patient's address, especially in cases where the boundaries of the boroughs run down the middle of the street, so that the odd numbers may be in one borough and the even in another. This meticulous accuracy is, of course, not superfluous, annoying though it may be, as boards of guardians can only provide for the residents in their own parish.

The removal of the infirmaries from the control of the boards of guardians and from the Poor Law and their centralization under the municipal authority will provide a system of municipal hospital accommodation as an integral part of the medical service of the country, supplementary to the general practitioner service of the National Health Insurance Act, and will have as its first result the abolition of the stigma of pauperism from the infirmary service. This centralization will also remedy the defect of the watertight compartments, thus making the municipal hospital service more fluid and efficient.

It appears to me, therefore, that the question of the future of the voluntary hospitals in relation to State and municipal services, except for the sectional activities which I have mentioned above, really narrows itself down to the future relationship of the voluntary hospitals to the infirmaries, if and when these infirmaries come under the control of the municipality.

I have mentioned above that there is often now little to choose between the services of the voluntary hospital and that of the infirmary. But there are differences, and it may be as well to consider what they are.

First, the fundamental difference between the Poor Law infirmary and the voluntary hospital at the present time is that the Poor Law infirmary has no out-patient department, or at any rate is not legally entitled to have one. Now it is the out-patient department of a voluntary hospital which causes the administration and the medical staff the greatest anxiety, for it is in that department that arises the great problem of the selection of those patients who shall be admitted to the hospital—that is, who shall be admitted and who shall be sent elsewhere. It is in this difficult task of selection that the voluntary hospital most commonly meets with public or municipal criticism, the question being asked why such and such a case was taken in and why such and such a case was sent away. The municipal infirmary has no such problem, as it has no out-patient department, and, as it is bound to take in every case that is sent by the voluntary hospital or by the medical practitioner, subject, of course, to the decision of the relieving officer, this problem of selection does not arise.

Secondly the voluntary hospital with a medical school does as a rule work at a higher professional standard and at a much higher pressure though as statistics as to the work of the municipal hospitals and Poor Law infirmaries are not, so far as I know available to the voluntary hospitals it is difficult to give chapter and verse for such a statement. But I think it is generally agreed that the cases in a voluntary hospital are on the average more seriously ill, and that the number of operations is proportionately higher in a voluntary hospital than in a Poor Law infirmary.

Thirdly there is usually a much more liberal provision of departments for special diagnosis and treatment in a voluntary hospital than in an infirmary.

The problem that we have to face at the present time is, therefore what is to be the nature of the co-operation between the voluntary hospital and the municipal hospital in the future? It is this problem of co-operation which appears to be causing so much alarm to many of the supporters of the voluntary hospital system.

I am a strong believer in co-operation, said the elephant, as it sat down on the pheasant's eggs in a prize-worth attempt to assist in hatching them out. Many of the voluntary hospitals look upon the municipality as the possible elephant in this scheme of co-operation and are afraid that with the unlimited funds which the municipality may obtain through the rates and other grateful municipal taxes, the municipal hospitals may eventually squeeze the voluntary hospitals out of existence.

I am not apprehensive of this result, and I do not think the Minister of Health or anyone else desires to destroy the voluntary hospitals. Mr. Neville Chamberlain himself discussing the future of the beds under the control of the municipal authorities and of the guardians has said in a recent speech with regard to the voluntary hospital beds and what was to happen to them: "Were they to be swallowed up by Lord Mayors and Mayors? Heaven forbid!"

I hold that if the voluntary hospitals continue to provide a medical and surgical service of the standard that they have hitherto provided at a cost which is less than or equal to, the cost of the municipal hospital service of the future they will survive. If they cannot then I think the time will come when the voluntary hospitals will have to go to the wall and the State or the municipality will swallow up the last remnant of a system that is peculiarly adapted to the British genius and that has been the foundation of British medicine and British nursing.

But to come to concrete proposals for co-operation between the municipal hospitals and voluntary hospitals. In this connexion I cannot do better than take as my text some questions which have been suggested to the British Hospitals Association by Sir Arthur Robinson of the Ministry of Health which as he says call for detailed and careful examination. Sir Arthur Robinson's questions are as follows:

1. Having regard to the nature of the hospital accommodation available in the area both in voluntary and public hospitals, are there any categories of cases which should so far as practicable be allocated to one type of hospital or the other?

2. Is it possible after taking stock of local need to agree on any lines of demarcation between the province of the voluntary and the public hospitals in the area?

3. Assuming that some understanding is reached as to the line of demarcation between the public and voluntary hospital in a given area to what extent would the modus schemes of enlargement in hand or in contemplation?

4. If there is a shortage of voluntary beds in what respect is the shortage most serious—for example, is it a shortage of general surgical or medical beds, gynaecological or maternity bed or orthopaedic? Is there vacant accommodation in public hospitals suitable or capable of being adapted for the type of cases for which accommodation is specially needed?

5. Could not some clearing house arrangements be established by agreement between the voluntary hospital authorities and the local authorities (including the guardian) which would ensure a better distribution of patients and the more rapid admission of cases requiring institutional treatment?

6. To what extent and under what conditions could the medical staff of the voluntary hospital undertake responsibility for cases or for a definite number of beds in public hospital so that the patient may be assured of the special type of experience required when medical or surgical without regard to whether the bed which he occupies is under voluntary or public management?

Let me, as my contribution to this discussion briefly set out how I should answer these.

1. Speaking as I have said before, especially on behalf of the voluntary hospitals with medical schools my answer must be "No," except that it is of course inevitable that the municipal institutions will receive a higher proportion of chronic and incurable cases than the teaching hospitals. To fill a teaching hospital with chronic cases is to sterilize medical education. It is essential that a hospital with a medical school attached must have the power and the opportunity to admit every type of disease whether trivial or serious, for this free selection of cases is of fundamental importance for the thorough education of the medical practitioner.

I have mentioned above the possible dangers to medical education of the existing municipal activities in the sectional treatment of disease in special hospitals. It is to be remembered that the function of the hospital with a medical school is analogous to the part which must be played more and more by the consulting physician in modern medicine, where specialism has developed to an equal extent. The tendency is growing greater every year for each specialist to look at every disease from the point of view of his own speciality. While specialism certainly improves technique and advances knowledge it also, unless carefully corrected tends to a restricted outlook, and there is therefore a greater need than ever for the general consulting physician who will so to speak put the jigsaw puzzle of all the various specialist opinions together and with the broadest outlook determine what is really the matter with the patient and what is the line of treatment which should best be followed.

Such also is the function of the general hospital—to ensure that investigators and workers in all branches of medicine shall work together in one institution and, by frequent consultation, ensure a broad outlook over the whole field of medicine and a judicious consideration of all the aspects of every individual disease.

2. I think this question must also be answered in the negative, as there are in parliamentary circles. I think it is impracticable to lay down definite regulations as to what a voluntary hospital or a municipal infirmary may or may not do. Can we say that the infirmary may operate on a simple case of appendicitis but must not do a gastro-jejunostomy, or that it may do a strangulated hernia and not a cholecystectomy? Such examples show how impossible such differentiation would be. Any attempt to interfere with the professional activities of the staff of the municipal hospital would be both impossible and disastrous. The medical staffs of the municipal hospitals must be in a position to perform any operation of medicine or surgery that is required for the necessary treatment of such patients as have been admitted. I am of course limiting my remarks to general medicine and surgery but the question does also arise as to whether the municipal hospitals will in any future schemes develop special departments for special regional diseases but it is clear that, in the main departments of general surgery, medicine and midwifery the voluntary and the municipal hospitals should, as far as possible be similar or not identical institutions.

3. As, in my opinion it is not possible to find any line of demarcation between the voluntary and municipal hospitals in a given area this question does not appear to arise.

4. There is a very definite shortage of voluntary beds, and speaking from my own experience at my own hospital I should say that the shortage is serious for general surgical cases—in some hospitals male and in some female cases—the surgical waiting list at most hospitals being considerable. The longest waiting lists however are in my own experience in the department for diseases of the throat and ear and for orthopaedics.

Whether we can ever really cope with the demand for beds for throat, nose, and ear patients is a question that I find almost impossible of solution and it will probably depend upon the future views of the medical profession as to the desirability or otherwise of removing the tonsils in nearly every living child or adult.

Orthopaedic beds are certainly hopelessly insufficient, principally because the proper orthopaedic treatment of a case is very often extremely long, and orthopaedic cases, therefore, occupy beds for a much longer period than the ordinary surgical or medical cases. If special provision could be made in the municipal hospitals for surgical, orthopaedic, and throat and ear cases, an enormous benefit would be conferred upon large numbers of the population who are now waiting week after week for beds in the voluntary hospitals. Moreover, in the interest of the public, it would be of inestimable advantage if more ample provision could be made for cancer cases, so that, if possible, there should not be a delay of more than a few days between the diagnosis of cancer and its removal.

Questions 5 and 6 must really be considered together. My ideal would be that the voluntary hospital with a teaching school should be the nucleus of the local hospital system, and should, to use a common phrase, be the "mother hospital" of the group. To ensure a proper co-operation between the hospitals in a district there must be no official machinery which will add difficulties or delay in the rapid transfer of patients from one hospital to another in the area—that is, it should be quite easy for the voluntary hospital to send a case to the municipal hospital, if there is no room for it in the voluntary hospital, and equally it ought to be as easy for the municipal hospital to transfer a case to the voluntary hospital, if there is not available in the municipal hospital the treatment necessary for the case. This can only be done if the voluntary and municipal hospitals are to a great extent under the same management. In this way alone can the perpetual discussion as to the relative rights and prerogatives of each institution be avoided.

The ideal would be that the voluntary hospital and the municipal hospital should be under some joint management both as regards the provision of the medical staff and the engagement and the training of nurses. I think it would be quite easy for the voluntary hospital to arrange for the delegation of a certain number of its visiting staff to act in a similar capacity at the municipal hospital. The municipal hospital would, of course, pay for these services, and a common visiting staff for the two institutions would ensure a common standard of treatment in each department.

In a short time the hospital-using public would learn to know that there was no essential difference between the voluntary hospital and the municipal infirmary, and, the stigma of pauperism having been removed, patients would not really mind into which department of a common institution they were admitted. Under some such arrangement it would, of course, be unnecessary for the municipal hospital to be provided with extensive laboratories for investigations, such as those which are now provided at the voluntary hospitals. Laboratory investigations for the municipal hospital could be done in the laboratories of the voluntary hospital, and by thus limiting the number of laboratories for investigations one could ensure the provision of sufficient investigations of the highest standard of knowledge and efficiency.

Assuming that this joint administration and co-operation comes into being, the final question which has to be discussed is: How is this conjoint institution to be managed? Is it to be managed by the municipality or by the voluntary hospital?

My own view is that the least destruction of the voluntary system and the greatest economy to ratepayers would be effected by the voluntary hospital having a predominant share in this conjoint administration. I take as my analogy the departments which I have mentioned previously in this paper—namely, the London County Council venereal disease departments, which exist now in many of the teaching hospitals. These venereal disease departments are managed entirely by the voluntary hospital, subject to inspection by the officials of the municipality. At the end of the year the hospital presents its bill, and the municipality pays it.

Surely this method could be amplified to include the management of the municipal hospital. The administration of the mother hospital would be responsible for the administration of the municipal infirmary, subject always

to the approval of the municipal authorities. The municipal authorities would be represented upon the governing body of the voluntary hospital, and in this way the municipality would not only have a very real control of its own hospital service, but would avoid the difficult task of instituting and maintaining a system of hospital administration parallel to and in competition with the voluntary hospital.

These ideas may be considered revolutionary, and may not meet with general acceptance, but I put them forward as concrete suggestions, as contrasted with pious generalities, in the hope that they may afford some basis for discussion.

## II—THE POOR LAW HOSPITAL AS A FACTOR IN PUBLIC HEALTH

BY

AL A REYNARD,

Chief Executive Officer of Glasgow Parish Council and District Board of Control

THE position of the Poor Law hospital as a factor in public health is a problem which is exercising a good deal of attention at present. There is an admitted shortage of hospital accommodation, and any scheme which might have the effect of meeting that deficiency should be cordially welcomed, and the possibilities of Poor Law hospitals have not been fully explored. The reason for the neglect of this avenue of relief probably lies in the hospitals themselves, as too often the hospital is an adjunct of the poorhouse, it is inadequately staffed with trained nurses, and the medical and surgical treatment is left to part-time men who never meet the councillors whose property the hospital is, consequently they do not have the opportunity of suggesting improvements, and so soon lose interest in the administration.

While it is true that these faults exist at present, they need not remain, in the Poor Law hospitals of Glasgow they have been eliminated, and the standard of efficiency in both medical and nursing staffs is equal to that of the voluntary hospitals. The hospitals are three in number, with accommodation for 2,400 patients.

Stobhill, which is the largest, has 1,700 beds. It was, during its period of military occupation, known as the 3rd and 4th Scottish General Hospital, and as such is familiar to most of my audience. The site is admirable—an eminence four miles north of the city. The buildings are of brick, with stone facings, detached wards of two stories are connected by a corridor to the operating theatres, to the administrative block, and also to the kitchen and recreation hall. There are isolated blocks, not connected by corridor, for the treatment of skin disease, mental observation wards, wards which are at present used for the treatment of encephalitis lethargica cases, with maternity blocks. In addition to the 1,700 hospital beds, there is accommodation for a number of children. This accommodation takes the form of separate villas. The children are placed under the care of a matron in each block and they live more or less in ordinary family life.

The hospital conforms as nearly as may be to a general hospital, such as the Royal or Western Infirmary in Glasgow. It is fitted with adequate operating theatres, an x-ray department, and general medical equipment, together with a fairly adequate electrical apparatus. Work is proceeding on a new theatre, an electrical department, and ear, nose, and throat, and eye departments, the total cost of which is estimated at no less than £35,000.

The grounds extend to about fifty-four acres. A bowling green, three tennis courts, and a recreation field have been provided for the use of the patients and staff. Fourteen gardeners and groundsmen are employed in the upkeep of the grounds.

The medical staff consists of a resident staff—medical superintendent with two permanent assistants, a whole-time pathologist with a whole-time assistant, together with twelve resident medical officers, who are engaged for a period of six months with a possible extension to two years. The wards for the treatment of the various diseases are placed in charge of visiting consultants as follows: two physicians, a surgeon, a gynaecologist and

obstetric surgeon, physician to children's department, physician to mental wards, eye specialist, aural surgeon, skin specialist, radiologist, dentist. Last year the total number of patients treated was 10,290. Duke Street Hospital, which is next in size, has accommodation for 314 patients. Oakbank, the smallest of the three has accommodation for 224 cases. Except for the smaller size, each of these hospitals is staffed and equipped similarly to Stobhill.

In the three hospitals the standard of medical, surgical, and obstetric treatment is quite equal to that of the larger voluntary hospitals. The council has recently appointed two officers who will be largely engaged in research work. The nursing staff, in whose training considerable pains are taken is as competent as any. This has been demonstrated in public examinations such as are held by the Central Midwives Board, the Medical-Psychological Association, the Board of Health, and the recently appointed General Nursing Council. Further, the supply of apparatus is being continually augmented.

The co-operation between the Poor Law and the public health authorities of Glasgow is good. Long prior to the extension of the ramifications of public health authorities many cases not treated by these authorities were treated in Poor Law hospitals. For example tuberculosis was, until a few years ago, dealt with mainly by voluntary hospitals and Poor Law institutions. Public health authorities now undertake the treatment of pneumonia and, more recently, of encephalitis lethargica. In Glasgow the institutional accommodation for tuberculosis and pneumonia is inadequate and the public health authority contracts with the parish council to deal with a proportion of the tuberculous patients in all of the Poor Law hospitals. At times of stress large numbers of pneumonia patients are frequently treated in Poor Law hospitals and, still more recently the parish council of Glasgow has placed at the disposal of all the public health authorities of Scotland certain accommodation in Stobhill for the treatment of encephalitis lethargica. The demand for the admission of encephalitis lethargica cases has been so great that only the most urgent cases are accepted, the procedure is that the medical officer of the district in which the case occurs makes application to the Board of Health who selects the cases and the accommodation officers, they are received into Stobhill. Quarterly reports on progress are made by the officer of the parish council to the medical officer concerned.

Two years ago the strain on the accommodation of the Glasgow Maternity Hospital was found to be more than it could bear, and, with the consent of the Board of Health, an agreement was come to whereby patients who make application to the Maternity Hospital and for whom no accommodation is available, are treated in Stobhill. The patients receive exactly the same treatment as is accorded to ordinary Poor Law patients, the only distinction being that their bed card is of a different color and bears a note that they are Maternity Hospital patients. The Maternity Hospital authorities repay the cost of board. About for patients a week are received and the arrangement has worked both satisfactorily and harmoniously.

At the present time negotiations are proceeding for co-operation between the education authority and the parish council for the treatment in Western District Hospital of children who require minor operations, such as the removal of tonsils and adenoids.

What has been accomplished in Glasgow can equally well be accomplished in other parts of Scotland, but the fact that it has not been brought about long ago is probably due to the unsatisfactory nature of the Poor Law areas. The parish is an area which has long outgrown its usefulness. The only merit which it has is that it is a known area but many parishes contain no more than a population of a few hundreds and it is absurd that the same legal machinery should be provided for a population of a few hundreds as is provided for a population such as that of Glasgow. If the areas were increased and the demand made on the Poor Law authority for hospital treatment it would be provided, but meantime the demand on each parish is so small that the parish council are only too ready to pass on their responsibilities to voluntary agencies.

A Royal Commission, under the chairmanship of Sir Donald MacLellan, whose report was issued in 1918 recommended a transfer of the functions of the Poor Law authorities to town and county councils. More recently Mr Chamberlain has framed a bill incorporating the proposals of this report. If such should become law it will get rid of the small areas and will place the responsibility for all hospital treatment on town and county councils. To be workable, the proposal would require to ensure that towns under a certain population are absorbed in a county area, and that a county under a certain population should be amalgamated with a neighbouring county.

It may be that town and county councils are not ideal bodies to undertake the functions of a hospital authority and arguments could be adduced for the creation of an ad hoc authority whose duty this particular function would be. In any event, the creation of a hospital authority for convenient areas would be an undoubted advantage, but some form of central control would be essential, and, for rural districts, assistance would be necessary from Treasury funds. The duty of the central authority could be to see to the erection of hospital in convenient areas, to decide on the standard of efficiency of rural hospitals, to exercise control over the erection of separate small hospitals in populous districts, and to encourage the amalgamation of smaller hospitals where the area is not too great.

If efficiently managed, a large hospital can be run at a much cheaper cost per patient per week than can a small hospital. In Glasgow, for the past year, the weekly cost per patient in Stobhill Hospital where the daily average number is 1,403, was 23s 4d, in the Eastern District Hospital with a daily average number of 241 the cost rose to 32s 1d, and in the Western where the daily average number was only 184, the cost amounted to 36s 2d.

Both local authorities and voluntary agencies are too prone to build institutional accommodation for themselves alone. Many small public health authorities have small infectious disease hospitals built for the accommodation of patients from their own area alone whereas they could quite easily have amalgamated with other authorities in the neighborhood and built a larger hospital where the costs, both for building and maintenance would have been much lower. Voluntary agencies are equally prone to fall into this error. In many cases the erection of a small local hospital is just as much the desire to erect a monument as it is to provide for the need of the population.

Motor transport has annihilated distance, and a mile or two further is a small matter in the days connected with what it was in the old days of the horse-drawn ambulance. The central authority might map out a scheme of hospitals for Scotland and arrange for the small cottage hospitals in rural districts to be linked up with the large hospitals in the city and ensure that at every small hospital motor transport is provided for the rapid transit of serious cases to a central hospital.

Hospital treatment is very largely a matter of specialization, and only in the large centres, such as the cities, do we look for medical men who have specialized in particular branches of medicine or surgery. The rural hospitals would require to depend very largely on the services of the local practitioners and efficient as such local practitioners may be their knowledge and skill can scarcely be expected to equal that of specialists attached to a central hospital who are dealing daily with the disease in which they have specialized.

A branch of hospital work on which I have scarcely yet touched is that of the observation ward for the treatment of incipient cases of insanity. Glasgow provides in the Eastern District Hospital 80 beds and in Stobhill Hospital 120 beds for the treatment of such cases. Unless the case is known to the inspector of poor or to the certifying medical officer as one of recurring insanity which has already been treated in a mental hospital, no patient is sent to such an institution without a probationary period which may extend in some cases to six months, in the wards of one of these general hospitals. The patients themselves show little or no aversion to going to a general hospital but, were they told they were being removed to a mental

hospital, their reluctance would probably be very forcibly shown. During the past year there were treated in the Eastern District Hospital 650 cases, and the number of recoveries without certification and without removal to mental hospital was 271. In Stobhill the results were even more satisfactory, the figures being 534 receptions and 340 recoveries.

While these satisfactory results are largely due to the skill of the specialists to whose care the patients are entrusted, it is also a fact that, except in the few places where such aids have been provided, patients suffering from minor accompanying or following pneumonia, puerperal fever, or alcoholism are certified "lunatic" and removed to a mental hospital, with the attendant notoriety and loss of self-respect on recovery. If hospitals were erected at convenient centres throughout Scotland, observation wards could be attached to each, and, in all probability, voluntary patients would much more readily attend there than they do at present in mental hospitals.

The creation of a hospital service for the whole country would probably have the effect of drying up much of the charity which at present flows to voluntary hospitals. By many this would be greatly deplored, but if some scheme can be devised whereby the cost of hospital service falls more evenly on ability to pay, there need be no great lamentation over the loss of charitable funds. The community in general is quite able to support an efficient hospital service, and if a system can be devised whereby those able to pay are called upon to do so, it will probably prove to be a fact that such a scheme would be welcomed by the very persons who at present contribute voluntarily, since they would know the extent to which they were morally and legally liable to subscribe.

At the present time nearly all the workmen employed in industrial concerns leave a portion of their wages, amounting usually to threepence a week, as a hospital contribution. In theory this is supposed to be voluntary, but, in effect, it is as much a tax as is their national health insurance contribution. To the individual with an income approximating £3 a week, threepence a week is quite a serious matter, much more serious than sixpence a week is to the person who enjoys a weekly income of £6, and very much more serious than a contribution of £100 a year is to the person with an annual income of £5,000 or £6,000.

The imposition of a tax based on the assessable value of the hospital area may not be exactly just, and may not get at the people who are most able to pay, but it is a known method of collection, and might easily be made in addition to the public health rate, against which there is at present very little complaint.

The system of imperial grants needs a radical rearrangement. At the present time Poor Law grants are block grants for Scotland, distributed on a basis of expenditure—that is to say, for the medical relief and trained sick nursing a sum of £20,000 is available, and this was, at one time, distributed according to the proved expenditure of each parish council, but in 1915-16 and in subsequent years, to obviate the necessity for yearly calculations, the basis of distribution was stereotyped. For many years prior to stereotyping, Glasgow, through the extension of hospitals and what was, in contrast to the other parochial authorities, a very superior hospital and nursing service, laid claim to and was paid almost all of the grant.

Imperial grants are intended to encourage the creation of a particular service, and after the service has been established and is a proved necessity the claim for imperial assistance largely vanishes. Glasgow cannot be said to be a necessitous area in so far as it is unable to bear the cost of hospital service, and a method other than the present might well be adopted for the allocation of the grant. In fact, if some standard of efficiency could be devised, the central authority might make payment of a grant or reward for attainment to this standard, and so encourage the managers of hospitals in local areas to be more progressive in their provision of hospitals, equipment, and staff.

Since the inception of the National Health Insurance Act, with the payment to panel practitioners of a yearly sum for each person whose name appears on their panel,

the claims on hospital accommodation have been materially increased. This is especially marked in the Poor Law hospitals of Glasgow, and evidence can be adduced to show that, in some instances, a panel practitioner who is likely to be called on to give personal service for a protracted period encourages patients who might quite well be treated in their own homes to apply for and accept institutional treatment. The voluntary hospitals are able to guard themselves against this imposition, but where the patient could command hospital treatment, as would probably be the case under the system which has been advocated of a hospital service for Scotland, there should be some standard of necessity for institutional, as against domiciliary, treatment, and an officer whose duty would be the discrimination of treatment of patients would require to be appointed. This should not be an insuperable task, as some of the Poor Law hospitals, particularly those of Birmingham, already accept patients from general practitioners without the necessity of application being made in the first instance to the central office of the Poor Law authority. Where such a system can be efficiently worked it is undoubtedly to the advantage of the patient, but it involves a co-operation between the officers of the Poor Law authority and the general practitioners, and it also involves the adoption of a policy which hitherto has not been enunciated in Scotland.

Where institutional accommodation is provided it invariably brings with it an increased demand, and to the central authority should be entrusted the task of framing a scheme for deciding which class of patients may be received and which class of patients may safely be left for treatment in their own home. The Board of Health is already undertaking this duty so far as encephalitis lethargica is concerned, and, while what is advocated will be a very much larger task, it should not be in any way beyond its ability.

The extension of hospital service will carry with it the creation of institutions for the care of incurables. At present the voluntary hospitals rid themselves of this class by passing them on in large numbers to the Poor Law institutions, which are left with a great many chronic patients who have no hope of ultimate cure, but whose condition requires nursing and attention.

An extension of convalescent homes would also prove of immense value, and if the patients can be persuaded to accept two or three weeks' treatment in a convalescent home after recovery from a serious operation, the advantage both to the patient and the community would more than repay the outlay involved.

#### DISCUSSION

SIR HENRY KEITH (Hamilton) thought that Mr. Dixon's proposal that voluntary hospital managers should have the predominant share in administering a hospital service might be expedient where the voluntary hospital was recognized locally as the outstanding agency for remedial medicine. But it would not be suitable in every administrative area. He believed that in the end the public health authorities were more likely to be the predominant partner. Hospital cases should be divided into those to be dealt with by public health authorities and those suitable for philanthropic treatment. The training of students, being work of national importance, should not depend solely upon the efficiency of hospitals supported by voluntary effort. The higher cost per bed in teaching hospitals justified a claim for State grants. The State was gradually imposing more clinical work upon municipalities, necessitating a closer co-operation of these authorities with existing voluntary hospitals. Sir Henry Keith thought that the development of transport facilities favoured the development of small institutions, without a full time medical staff, since access to special departments in populous centres became easy. He quoted figures from reports on the cost per patient in voluntary hospitals in England and Scotland, to show that Mr. Reynard was in error in suggesting that large institutions were more economical than smaller hospitals. Scotland had, proportionately, many more beds in voluntary hospitals than England. This might be due to the Scottish municipalities having no statutory authority

for establishing general hospitals. Sir Henry Keith hoped that voluntary hospitals would be left to pursue their beneficent work unhindered, that if financial insufficiency arose the public health authorities should be enabled to come to the assistance of well equipped voluntary hospitals, and that if they did so there should be some representation of the employers on the management of the hospital. In proportion to the financial instability of the institution the public health authorities could gradually assume control.

Dr J P KINLOCH (Aberdeen) described the taking over from the parish council, free of charge, of the Poor Law hospitals by the town council of Aberdeen. The hospitals had now functioned as modern municipal hospitals. It had been found essential to secure co-operation with the voluntary hospitals and with the University medical school. All the voluntary hospitals were now being transferred to a common site, whereon would be established new university departments of medicine, surgery, midwifery, and pathology. Co-operation was to be effected by allowing for the municipal hospitals the consultative services of the professors of medicine, surgery and midwifery, an offering to the University medical school the freest access to the municipal hospitals for teaching and research. Interference of administration was not required. Dr Kinloch thought it quite unnecessary for the medical personnel to take sides in discussing the spheres of action of two administrative bodies. The medical personnel should be content if all its reasonable requests were granted. Fever hospitals should be more fully used in the clinical instruction of students, especially now that an increasing variety of acute medical cases was being admitted to these institutions. A third of the work of the general practitioner was concerned with acute infections, and these could only be studied in fever hospitals.

Parish Councillor A D DOUGLAS (Edinburgh) stated that the problem was not raised by present-day parish council administration, which was undoubtedly successful and generally approved. The two hospitals in Edinburgh were highly efficient and fully equipped. Too much was being made on the one hand, of the prejudice against entering a Poor Law hospital, and on the other, of the feeling in favour of the continuance in its present form of the voluntary hospital. If there was so much difficulty in carrying on voluntary hospitals he thought that the management should be given over to the municipality.

Dr H B BRACKENBURY (London) said that the general practitioner must not be overlooked. The Representative Body had this year again drawn attention to the fact that both the hospitals and the public health authorities had, perhaps inevitably, been encroaching on the sphere of private practice, and the last thing that was desirable was that they should combine for the purpose of making these encroachments more extensive. In this regard the practitioner was concerned not merely with the narrowing of his field of practice but with securing adequate treatment for his patients, and with maintaining his own efficiency and that of his successors in the profession. To this end two things at least were essential. (1) the grouping of hospitals, (2) the admission of the general practitioner to the observation and exercise of such forms of hospital practice as he could properly undertake. On the one hand the teaching hospital must freely admit all types of case to some extent, and must have grouped with it institutions for post-operative treatment, for convalescents, for chronic cases, and for incurables because for all these classes or else the general practitioner would be almost wholly responsible, though not for these alone. On the other hand with the large provincial general hospital must be grouped the smaller hospitals within a suitable area, the work of these latter being in the hands of general practitioners. Dr Brackenbury thought that the total shortage of hospital beds would not be found to be quite so great as had been stated if there were proper grouping and if there were a confinement of institutional treatment to those classes of case which could not be dealt with in other ways. In the present transitional period it was desirable, at least until the needs had been

more closely determined, that neither of the two groups of hospitals should be too rigidly organized, or that their relations with the local authorities should be quite fixed. They might well remain under voluntary management by experienced boards such as those which now managed the central hospitals of such groups, work done for the public authorities being paid for at agreed rates year by year.

Sir NORMAN WALKER (Edinburgh) said that the amount of co-operation—much legal, some illegal—was already going on. He recalled a statement from an American source that the more teaching there was in a hospital, the better the treatment of the patient. The doctor must gain his knowledge from the chronic case. It was two senior assistant physicians were seconded to the parish council hospital, and returned to the Royal Infirmary when their time came to be senior physicians. Co-operation would be effected. Provision for incurable cases was inadequate. Something like grading of cases would be useful as it was not fair that certain operations should be performed in cottage hospitals.

Dr DUNSMOND SMITH, M.P. (Edinburgh) said there had to face the fact that there were heavy waiting lists in the voluntary hospitals involving lack of urgently required medical and surgical care for large numbers of people. Many of these hospitals were also badly equipped. The voluntary system had done a great and beneficent work, but flag days and student stunts were not desirable ways of making provision for the sick in the community. He had no particular objection to them for supplementary purposes, but the preservation of efficiency should not have to depend on them. The voluntary principle had been modified in many directions. In Edinburgh Royal Infirmary the annual income was £130,000, of which £35,000 was got by a voluntary levy on workmen, the money being deducted from their wages each week. If the community believed that hospitals were necessary, it did not matter whether the necessary money was handed to a collector on the street or paid with the rates. Municipal isolation hospitals were generally efficient, and there was every reason to believe that general hospitals under the same management would be equally efficient, and not starved as many of them were at present. The position of medical staffs would not be essentially different from the present arrangements, except that the resident posts would have reasonable remuneration, which would enable teaching schools to have at their command promising juniors who were at present often lost. In the smaller hospitals, general practitioners should be employed when possible as part-time medical officers. The fact must be frankly faced that in the evolution of things some form of municipal hospital was inevitable.

Dr A S M MACCORMACK (Glasgow) criticized Mr. Enson's proposal to hand over the administration of hospital services to voluntary hospital managements. He thought that no such body would be able to visualize the whole needs of a city. He asked what would happen if such a body failed to concentrate upon some of the needs.

Dr STELLA CHURCHILL (London) believed that there were in infirmaries 20,000 beds empty in the winter months and 30,000 in the summer months. It would be better to equip and maintain such infirmaries adequately rather than build new voluntary hospitals at great expense. Voluntary associations should no longer be allowed to put up specialist hospitals wherever they pleased. In London it was possible to find several specialist hospitals in the same street with a big general hospital. It had been stated that 7 beds per 1,000 of the population were required in this country, but in Copenhagen the number was as high as 8.5. In the large municipal hospital at Amsterdam all types of diseases were housed under the same roof, thus promoting economy and efficiency in administration. She failed to see why money derived from municipal sources would be badly expended, and thought that some form of democratic representation on the management boards of voluntary hospitals would have long ago protested at deficiencies such as the lack of maternity beds. Insured

poisons should not be required to pay a double levy in the form of a hospital contribution in addition to their national health insurance. She deplored the amount of time and energy spent in organizing hospital carnivals, and in raising money in other even less reputable ways in aid of the voluntary hospital system.

Dr A. MAXWELL (Birkford) thought that the teaching centres had received more than their share of the discussion, to the exclusion of large centres of population where there was neither university nor medical school. By way of illustration he gave some account of the existence side by side in a large industrial centre of voluntary hospitals and a large municipal hospital. Here there were 142,000 insured persons in a total population of 289,000—almost 50 per cent. The Royal Infirmary had a waiting list, and the municipal hospital received both civic and Poor Law patients. There were also a children's hospital, the Royal Eye and Ear Hospital, and a cancer home, all on a voluntary basis. The municipal hospital, springing out of the war hospital and Poor Law infirmary, undoubtedly filled a gap, but there was great faith in the voluntary system, which was not regarded as being in any way played out, in fact, there was an appeal proceeding for a large sum of money to erect an entirely new Royal Infirmary, and building was soon to be commenced.

Mr Eason, in reply, said that the discussion had been very interesting, and only showed how important it was that the far-reaching consequences of Mr Neville Chamberlain's proposals should be thoroughly considered by all who might be concerned. It was also quite clear from the discussion that, as he had indicated in his paper, a uniform system would not be suitable for every town or every district, and that he, in his paper, was speaking for London and London alone. He also wanted to make it clear that he was not holding a brief for the voluntary system. He was merely speaking, as he had been requested to do, on the relationship of the State and the municipalities to the voluntary hospital system, should the voluntary hospitals continue as such. It might be, as he had suggested in his paper, that sooner or later the voluntary hospitals would disappear and be replaced by State institutions. If and when such a change did come his sincere hope was that the State hospitals would prove as efficient and popular as other State institutions—for example, the post office telephone system.

Mr M. A. RYLAND doubted whether the small and cheaply run hospitals advocated by Sir Henry Keith could show the same competence and efficiency in the medical and nursing staffs as the larger institutions.

## ACUTE PNEUMONIA IN EARLY CHILDHOOD

### I.—INCIDENCE AND MORTALITY OF THE DISEASE IN EARLY INFANCY

BY

CHARLES McNEIL, M.D., F.R.C.P. (Ed.)

Physician, Royal Edinburgh Hospital for Sick Children

In opening this subject of acute pneumonia in children I propose to dwell on one or two of its general aspects, which I hope may lead to further discussion. The subject is a wide one, and has of course, many other aspects and points of interest. Some of these, no doubt, will be dealt with by subsequent speakers.

The great frequency of the disease in the wards of children's hospitals allows the presentation of a great number of cases, and many large statistical surveys have been made. Those of Dunlop, compiled in the Edinburgh Children's Hospital, and of Holt in New York, are well known and much quoted. For the purpose of this discussion I wish to use a series of my own cases, a total of 558, of acute pneumonia admitted to my ward during six and a half years. In the following tables, I have

arranged these figures in a particular way in order to bring out certain facts as to pneumonia which seem to be worthy of consideration and discussion. In this study of pneumonia my two colleagues at the hospital, Dr Agnes Macgregor and Dr W. A. Alexander, have been associated with me, both in clinical examination of special or typical cases and in discussion together, they have also made themselves specially responsible for the pathological investigations, both as regards morbid anatomy and microscopic studies. We have also had the assistance of Lieut. Colonel W. Glen Iston in bacteriological investigations of a considerable number of cases, both during life and after death.

Before giving the two tables of figures, one or two explanations of them may be made. I have grouped together all cases of acute pneumonia, not making the usual division into lobar and broncho-pneumonia. The reasons for this will be given later in discussing the clinical and the pathological differentiation of these two clinical types of pneumonia. Also, while giving in a separate list the cases of empyema admitted to my ward during the same period, I have in the third column of each table added the figures of empyema to those of pneumonia. Practically every case of empyema follows pneumonia, and it seems to me that my statistical survey of pneumonia is incomplete without inclusion of empyema. These figures of empyema include some cases discovered only after death, even where the effusion was small and the pneumonia minor and acute, they also include one or two cases of small non-purulent pleural effusion containing pneumococci and associated with definite pneumonia. They therefore represent as completely as is possible a list of cases of pneumonia complicated by inflammatory pleural effusion.

TABLE I—Cases of Acute Pneumonia in the Balmgate Ward of the Royal Edinburgh Hospital for Sick Children, 1920-1927

Age Period	Acute Pneumonia		Empyema		Combined Groups Acute Pneumonia plus Empyema	
	Cases	Deaths per cent	Cases	Deaths per cent	Cases	Deaths per cent
First year	110	40.0	9	77.7	119	42.8
1-2 years	145	18.5	14	42.8	160	20.6
2-3	70	11.4	9	11.1	79	11.4
3-5	70	4.0	4	50.0	80	6.2
5-12	95	1.0	25	4.0	120	1.6
Total—Birth to 12 years	497	16.7	61	26.2	558	17.9

TABLE II

Age Period	Acute Pneumonia		Empyema		Combined Groups Acute Pneumonia plus Empyema	
	Cases	Deaths per cent	Cases	Deaths per cent	Cases	Deaths per cent
First 2 years	256	27.7	23	56.5	279	30.1
2-12 years	241	5.0	38	10.5	279	5.7

The first table, giving the numbers of cases of pneumonia and empyema at successive age periods from birth to 12 years, makes clear two facts as to pneumonia already well known—the very high death rate in the first two years (42.8 and 20.6 per cent) falling rapidly thereafter to a quite low figure after five years (1.6 per cent) and also the less striking but still definite fall in the frequency of the disease after the first two years. Although acute pneumonia after the first two years is outside our present discussion, two points seem to be suggested by a comparison of the figures of pneumonia alone and of pneumonia plus empyema. The death rate in the complete group of pneumonia plus empyema is not greatly higher than in that of pneumonia alone. In the first two years the figures no doubt show a much higher death rate for empyema than for pneumonia, but this may well be explained by the severity of the accompanying pneumonia at this period. The figures, therefore, support

\* The opening paper of a discussion in the Section of Diseases of Children at the Annual Meeting of the Association of Paediatricians, Edinburgh 1927.

the statement that has been made in recent discussions on emphysema—that in this disease the death rate is largely determined by the severity and extent of the underlying pneumonia and by the age of the child. Also this series of figures suggests that emphysema is a commoner complication of pneumonia after five years than before—1 in 5, as compared with 1 in 10.

The second table is constructed to emphasize the fact that the mortality and frequency of acute pneumonia, including emphysema, are much greater in the first two years of life than in the succeeding ten, there being an equal number of cases (279) in these very unequal age periods and strongly contrasted death rates of 30.1 and 5.7 per cent. The rate of death in pneumonia plus emphysema in this series of 553 cases from birth to twelve years may be put in another way equally striking. There were 100 deaths in all of these, 84 occurred under 2 years (279 cases), 14 from 2 to 5 years (159 cases), and only 2 over 5 years (120 cases). These figures give percentages of 30, 9 and 1.5 as shown in the accompanying diagram.

the disease that it is more common and far more deadly in the first two years of life than in the succeeding years of childhood. The facts suggest an obvious question. In these cases of fatal acute pneumonia, what is the prevailing pathological type, lobar pneumonia or broncho-pneumonia?

#### LOBAR PNEUMONIA AND BRONCHO-PNEUMONIA

The general and accepted teaching is that broncho-pneumonia is much commoner and also much more fatal in the early years of childhood. But the figures given as to the comparative frequency of these two types of pneumonia vary widely and these figures are based on clinical criteria which either vary a good deal or are vaguely stated. The statement is also frequently made that *post-mortem* examination often shows one type where the clinical examination has suggested another. Yet in medical textbooks and in the clinical statistics referred to, no author at present is made as to the frequency of the two types: lobar pneumonia and broncho-pneumonia, as shown by a large series of *post-mortem* examinations. Dr. Agnes Macgregor has investigated this point in 100 cases of fatal pneumonia, and her results give an accurate idea of the parts played by lobar pneumonia and by broncho-pneumonia in these fatal cases.

For the purpose of my contribution to the discussion I will anticipate her results only so far as to say that in fatal cases lobar pneumonia is compared with broncho-pneumonia as a rare disease. It is broncho-pneumonia which is the death-producing type in the first two years of childhood. But it need not follow that this proportion also obtains in the cases of pneumonia that recover.

#### Pathological Characters

It will be useful here to outline briefly the pathological features of the two types of pneumonia. If the pathological feature can be clearly distinguished we are more likely to obtain satisfactory clinical methods of recognizing them. The terms "lobar pneumonia" and "broncho-pneumonia" are unsatisfactory, but until better ones are adopted they must serve.

Lobar pneumonia, as a pathological process, is the simpler type. As a result of inflammation a fibrinous exudate is

poured out into the alveoli, but at this stage and later, the framework of the lung, including the bronchial walls, seems to be undamaged. At the end a rapid resolution of the alveolar exudate takes place. In children there is a great variation in the extent of consolidation and in many cases only a small portion of a lobe is involved, while in not a few clinical examinations can detect no area of consolidation. For this reason alone the term lobar is unsuitable. We would suggest that "alveolar pneumonia" is a more accurate description of the pathological process, and explains better its clinical course.

Broncho-pneumonia is a more complicated process, and also shows much variation in the extent and nature of the morbid changes. Here in addition to a varying type of exudate in the alveoli and bronchi, the interstitial framework of the lungs—the bronchial and alveolar walls—show inflammatory change. It is usual to make a broad division into primary broncho-pneumonia where the process is supposed to begin within the lung as does lobar pneumonia, and secondary broncho-pneumonia where it follows bronchitis, as in influenza, measles, whooping cough, etc. In either case interstitial inflammation is an essential and important feature of the process. We would suggest that "interstitial pneumonia" is a better term than "broncho-pneumonia" for it is this interstitial inflammation which determines the longer course of the disease, its greater immediate danger of extensive and fatal spread, its greater risk of permanent damage to the lung tissues in fibrosis, bronchiectasis and bronchiectasis. The term "interstitial broncho-pneumonia" has already appeared in medical and pathological textbooks to describe certain special types of broncho-pneumonia secondary to measles and influenza. Interstitial pneumonia seems a suitable term to describe all cases of broncho-pneumonia.

#### Clinical Features

Many points are given which may enable us to distinguish in life the two types of pneumonia—lobar (alveolar) pneumonia and broncho-pneumonia (interstitial). Thus in broncho-pneumonia we are said to have a slower onset, an antecedent bronchitis with cough prominent, of cough throughout, cramps and more difficult breathing, a less regular and sustained febrile curve, evidence of widely dispersed consolidation and extension of the lung, a longer duration of illness, a slow resolution. Lobar pneumonia is distinguished by its sudden and severe onset, its high sustained fever, a short course of a week or little more, the limitation of consolidation to one area, the dramatic termination of fever by crisis, the rapid resolution of inflammatory product. But some of these distinguishing signs may fail or may appear in a contradictory way. I would suggest that the cardinal differential sign between these types of pneumonia are only two: the duration of fever and the rapidity of resolution—long fever and slow resolution in broncho-pneumonia, short fever and rapid resolution in lobar pneumonia. Fever and consolidation persisting over a period of two weeks may be taken as indicating broncho-pneumonia. None of the other points mentioned are diagnostic.

#### Confluent Broncho-pneumonia and Chronic Pneumonia

In spite of much variation in the clinical features the differential diagnosis of lobar pneumonia and broncho-pneumonia is not difficult in many cases. But there is one clinical type of broncho-pneumonia which is not uncommon and which presents difficulty—namely where there is extensive consolidation limited to one area of the lung. This is the type sometimes described as "confluent broncho-pneumonia." Such cases, showing clinically an extensive pneumonia in one lung and the other apparently healthy if they die in about a fortnight, are apt to be diagnosed as lobar pneumonia, yet autopsy shows a massive broncho-pneumonia on one side and generally also small scattered areas of pneumonia in the other lung which seem to be of more recent date. These cases of rapidly fatal confluent broncho-pneumonia are I think especially frequent in the first year of life, they are usually accompanied by early emphysema. In no way—neither in the manner of onset nor in their clinical features and physical signs—can they be distinguished in life from lobar pneumonia.

We have seen that the pathological process in broncho-pneumonia has a longer course than in lobar pneumonia. Therefore if the child survives, broncho-pneumonia is a more chronic disease than lobar pneumonia, and the course of a recovering broncho-pneumonia may extend over months. We are all familiar with such cases, both of primary and secondary broncho-pneumonia, they are, indeed, cases true to their type, both in their long course and the disseminated character of the pneumonia. But there is also a definite and not small group of cases of localized and chronic pneumonia, these are variously named unclassified, subacute, or chronic pneumonia, and they are generally classified as belonging to the lobar type. May they not rather be regarded as cases of broncho-pneumonia, similar to, but less severe than, the fatal cases of massive or confluent broncho-pneumonia just described, and where a primary broncho-pneumonia has spread locally and has not assumed its usual disseminated character? The following case is an example of this kind.

A female infant aged 8 months, was admitted to hospital on November 1st, 1925, with a history of cough and slight malaise for two weeks, and of difficult breathing and prostration for two days. For the next two months she had intermittent bouts of fever with signs of pneumonia first in left lower and then in right lower lobe, and followed by resolution. A third area of pneumonia then appeared in the right upper lobe and slowly extended over the whole right lung. In March, 1926, a localized empyema was found in the right upper lobe and was treated successfully by repeated aspiration. Signs of resolution began in May four months after the onset of the last attack of pneumonia, and proceeded for two months, the lung clearing from base to apex. Thereafter convalescence was steady, with a little residual dullness at the apex, shown only on x-ray examination. The period of fever and consolidation of lung had lasted for eight months.

This is an extreme case of chronic pneumonia with the additional complication of empyema. But in my large series of cases of pneumonia in children there will be found a definite group of this kind, where both fever and consolidation persist for a long time, and where resolution is slow.

I would, therefore, submit for discussion a statement that in cases where pneumonia has lasted more than two weeks the process is not confined to the alveoli, interstitial inflammation has taken place, and we are dealing with a process of broncho-pneumonia, however circumscribed or small the area of consolidation may be.

Until clinicians are agreed on the clinical signs which distinguish these two types of pneumonia we must expect to have widely differing clinical estimates of their frequency. And for this greater accuracy of clinical diagnosis we need also to know more of the pathology and the bacteriology of broncho-pneumonia in children. Meantime, it would be some advantage if we ceased to use such terms as lobar pneumonia and broncho-pneumonia, which do not convey to the mind accurate ideas of the morbid processes taking place in the lungs. After our decision as to the site and extent of pneumonia, instead of fixing this misleading label, we should rather try to determine the parts of the lung affected by the inflammation—bronchi, interstitial tissues, alveoli, pleurae.

#### *The Explanation of the Frequency of Broncho-pneumonia in Early Childhood*

We have seen that the large majority of the deaths from acute pneumonia in children occur in the first two years of life (84 per cent.), and Dr Macgregor will give figures to show that the type of pneumonia in the greater number of these cases at this age is that called broncho-pneumonia. Have we any satisfactory explanation why pneumonia, which is so frequent at this age and in the hospital class of children, tends so often to assume this fatal broncho-pneumonia type? That is a question which deserves examination, but which is difficult to answer.

Does the explanation lie in a special bacterium or virus? Now the recent experience of the great camp epidemics of broncho-pneumonia following measles and influenza during the great war seemed to establish the connexion of certain types of broncho-pneumonia with certain kinds of bacteria. MacCallum particularly has taught that the nature of the organism might be predicted from the visible character of the lung lesions. It can hardly now be doubted that types of broncho-pneumonia in the adult are produced by

different organisms from those that produce lobar pneumonia. And in a considerable number of the cases of the present series of acute pneumonia in children, Colonel Glen Liston has found *B. influenzae*. Further bacteriological research in the broncho-pneumonia of children may well yield important results.

But whether the causal organism be pneumococcus or streptococcus or influenza bacillus, it seems difficult to explain by bacterial agency alone the fact of the high mortality and frequency of the disease at a special age period. Among other possible factors, the mysterious but powerful influence of constitution may play an important part. By constitution is meant the inherent nature of the lung tissues at this early age, rendering them prone to bacterial infection, and favouring also this interstitial type of inflammation which we call broncho-pneumonia. This is no new theory. It is also not a question of special inherited diathesis, but of the natural "disposition" or constitution of the human body at this age. This constitution varies with age, and its various manifestations are to be seen both in the differing states of health and the changing reactions of disease at different ages of human life. Growth is rapid in the infant, it becomes slower in the child, in adult man it has ceased. The lymphatic system, the pulse rate, the whole system of nutrition and metabolism, change as life proceeds on its course from infancy through childhood. This changing constitution finds equal expression in disease. Cancer is common at 50 years of age, and rare at 5. Rheumatic infection does not plant itself in the body of the infant and young child, in the child of 5 it secures a hold, but produces a type of disease reaction very different from that in the adolescent. So it may be that the common agent of pneumonia in man, the pneumococcus, tends to produce in the lungs of the youngest children a type of inflammation which we call broncho-pneumonia, that this tendency definitely weakens after two years, but is still evident until later childhood, say five years, and that after this age the reaction changes to the extensive alveolar exudation with little or no interstitial inflammation which we call lobar pneumonia.

But this influence of a natural age constitution is not sufficient. For pneumonia is rare in healthy and well-cared-for children of any age. There must also be a deterioration of living function produced by bad environment and hygiene, and the influence of climate and season also comes into play.

It is therefore apparent that the problem is a complex one in which there is the intricate play of many factors. At present we are not able to say definitely what these factors are, and what is then relative importance. But the high death rate and the frequency of broncho-pneumonia in the first two years of life make it a subject worthy of study and discussion, and it is particularly by further study of its pathology and bacteriology that we may hope to gain more knowledge of the disease and more control over it.

## II—PATHOLOGY OF ACUTE PNEUMONIA IN EARLY CHILDHOOD

BY

AGNES R. MACGREGOR, M.B., CH.B.,  
M.R.C.P. Ed.,

Assistant to the Professor of Pathology, University of Edinburgh

**DIFFERENTIATION** between lobar pneumonia and broncho-pneumonia by pathological examination in fatal cases is usually a matter of no great difficulty, for most cases exhibit well defined features which enable them to be placed in one or other of these two classes. Occasional cases, however, possess atypical characters and present difficulty in classification.

#### *Definition of Terms*

The term "lobar pneumonia" is applied to cases in which there is a circumscribed area of lung tissue completely and uniformly consolidated. The area may be of the extent of one complete lobe, or more, or less. Scattered patches of pneumonia in addition to the main area are absent. Bronchitis is usually little in evidence.

The term 'broncho-pneumonia' is applied to cases in which pneumonia occurs in patches surrounding bronchi and bronchioles, either without or with confluence, the latter may lead to massive consolidation of parts of the lungs. Inflammation is more intense in alveoli closely related to bronchi. The bronchi themselves are much inflamed.

Differences in the character of the exudate are of small value in distinguishing the types. While as a rule the exudate of lobar pneumonia is more fibrinous and that of broncho-pneumonia richer in cells, this difference is not constant.

#### *Incidence of the Types*

The incidence of the types in 100 consecutive cases of pneumonia in children examined post mortem at the Royal Edinburgh Hospital for Sick Children was as follows.

**Lobar Pneumonia**—This group was represented by 11 cases, of which 8 were typical, 3 being somewhat atypical but possessing chiefly the features of lobar pneumonia. Of the 11 cases 3 were bilateral. The eldest patient was 4½ years of age, the youngest 6 months, the average age was 17 months. Six were under 1 year, between 1 and 2 years.

**Broncho-pneumonia**—This group was represented by 89 cases of which 3 were somewhat atypical. Of the 89 cases 79 were bilateral, in 11 of these one of the lungs was relatively slightly affected and in 63 the disease was extensive in both lungs, 69 showed massive confluence in one or more lobes, 20 showed no confluence in any considerable area. The eldest patient was 6 years of age, the youngest 3 weeks, the average age was 14½ months. Forty three were under 1 year, 29 between 1 and 2 years.

These figures show that in a series of fatal cases, (i) 81 per cent of all the cases were in children under 2 years of age, (ii) 89 per cent were cases of broncho-pneumonia, (iii) 89 per cent of the cases of broncho-pneumonia were bilateral, while less than one-third of the cases of lobar pneumonia were bilateral, (iv) 77.5 per cent of the cases of broncho-pneumonia were of the confluent type and exhibited massive consolidation in at least one lobe. This is an outstanding difference between broncho-pneumonia in children and in adults, confluent consolidation being relatively uncommon in the latter. It is important from the clinical point of view, as it introduces a difficulty in differential diagnosis during life.

At autopsy confluent broncho-pneumonia is distinguished from lobar pneumonia chiefly by the following features: (1) The massive airless portion is usually of less uniform consistency in broncho-pneumonia, and is produced by a combination of consolidation and collapse. (2) On section its appearance is not uniform, it shows mottling usually yellow, around the bronchi. (3) Usually it is defined less sharply than is the case in lobar pneumonia, and shades off into indefinite patches at the edges. (4) In addition discrete patches of broncho-pneumonia are present in other parts. (5) There is a more or less diffuse acute bronchitis.

A fact which ought to be emphasized is that broncho-pneumonia, at least in fatal cases, is of very much more widespread distribution than the average fatal case of lobar pneumonia. Often lobar pneumonia is confined to one lobe of the five. Broncho-pneumonia, whether with or without confluence usually attacks all five lobes and the inflammation is at different stages in the various parts. The very extensive involvement of the terminal airways which results accounts for the severe respiratory embarrassment which characterizes the clinical picture of broncho-pneumonia.

#### *Microscopic Pathology*

During the course of the research on which this communication is based a series of cases has been studied with the aid of paraffin sections extending to a whole lung. These sections can be examined under high power, or the microscope, and thus are of great value in the investigation of the distribution of inflammatory changes in various forms of pneumonia. The conclusions which are here stated have been drawn largely from a study of these sections. This study has revealed certain important differences between lobar pneumonia and broncho-pneumonia.

In lobar pneumonia as seen in the human subject, the freedom of the connective tissue framework and lymphatic

system of the lungs from inflammatory infiltration is a remarkable feature. There is no persistent lymphangitis, the inflammation is located in the alveoli, whose walls possess no lymphatics. The alveolar septa show congestion, oedema, desquamation of epithelium but the exudate is poured out into the alveolar spaces and the walls do not suffer disorganization. When recovery occurs the products of inflammation are removed by resolution. There is no occasion for a process of reorganization which would bring about permanent changes in structure and inevitable disorganization of function.

In broncho-pneumonia it is usual to find a large amount of inflammatory infiltration of the substance of bronchial walls and of alveolar walls in the centre of pneumonic patches. In the area of an early lesion on a bronchiole is present with catarrhal contents in its lumen and inflammatory infiltration in its walls and in the peribronchial lymphatics (in the severer cases the infiltrating cells are mostly polymorphs). This is surrounded by a group of consolidated alveoli whose walls are also infiltrated, and often infiltration of the walls seems to precede consolidation of the lumen, and extends beyond the edge of the consolidated patch. It is therefore evident that infection reaches these alveoli through the bronchus wall and along the alveolar septa, and not by continuity of lumen. Acute interstitial inflammation is an essential part of the process.

There may be in addition directly connected with this hyaline expansion of lumen, consolidation in the terminal alveolar expansions of the central bronchiole. When there is confluence this is always present but the interstitial inflammation persists in the peribronchial zone, and produces the mottled appearance noted on naked eye examination.

Cases exhibiting acute interstitial inflammation and lymphangitis have been described by some authors as a special type which they call acute interstitial pneumonia. We have found it to be practically constant in our cases, and have come to regard it as the characteristic lesion of broncho-pneumonia. We believe that the cases described under this name are those in which interstitial inflammation is particularly obvious and alveolar inflammation more or less in abeyance, but that the difference between these and other cases is merely one of degree and that the presence and importance of acute interstitial inflammation in all cases of broncho-pneumonia have not been sufficiently recognized.

In the involvement of the framework of the lung lymphangitis plays an important part. In ordinary cases of acute broncho-pneumonia it appears as a crowding of lymphatic channels with inflammatory cells sometimes causing enormous dilatation of the larger vessels. It begins in peribronchial lymphatics but soon spreads to perivascular and septal lymphatics also and extends gradually in progressive fashion to all parts of the lungs.

We believe that the existence of progressive lymphangitis in broncho-pneumonia accounts for the firm hold which the infection gains upon the lungs and that the absence of it in typical lobar pneumonia favours rapid and perfect recovery from the effects of inflammation.

It has, however, been claimed by Blake and Cecil that lobar pneumonia experimentally produced in monkeys begins as a primary lymphangitis to which alveolar inflammation is secondary. Further, they state that this lymphangitis passes off with the onset of lobar consolidation of the alveoli. The application of this result to human cases has yet to be demonstrated, but if it be correct it would seem to follow that broncho-pneumonia results from persistence of the primary lymphangitis.

The question arises whether all cases in which the features of confluent broncho-pneumonia are present at the time of death have possessed those features from the outset. This is important in connexion with the problem of differential diagnosis of lobar pneumonia and broncho-pneumonia during life, and the difficulty of placing certain cases in one or other of the two groups. It seems not unlikely that the lymphangitis which leads to broncho-pneumonia might develop either from bronchitis or from a localized patch of primary pneumonia. In certain cases of localized pneumonia of lobar type lymphangitis may supervene at a later development, and lead to a subsequent spread of inflammation throughout the lungs, after the manner of

**broncho-pneumonia** Such a case would be classed as confluent broncho-pneumonia at necropsy, and some fatal cases of primary pneumonia which clinically are thought to be lobar, but at *post-mortem* examination are found to be confluent broncho-pneumonia, may perhaps be explained in this way.

To sum up we regard acute broncho-pneumonia as the result of progressive invasion of the lymphatic system and interstitial framework of the lungs by the infective agent, in other words, as the result of failure of the lymphatic apparatus to defend itself against invasion.

#### *Some Further Effects of Lymphangitis*

It is widely recognized that broncho-pneumonia is more apt than lobar pneumonia to cause serious damage to the lungs, and to be followed by various undesirable results. Among the most important of these are suppuration, bronchiectasis and fibrosis of the lungs. All these may be directly attributed to effects of lymphangitis.

#### *1 Suppuration within the Lungs*

As a development of broncho-pneumonia this occurs in two distinct forms.

(a) Originating in bronchial walls, as a direct result of suppurative lymphangitis in peribronchial lymphatics. This seems to be not very uncommon in fatal cases. In our series it has been most often associated with empyema. We believe that the interference with lymphatic drainage which results from compression of the lung by a pleural effusion definitely favours the development of suppuration in the lymphatics. Suppurative lymphangitis, though most common in peribronchial lymphatics, may also cause diffuse suppuration along lymphatic paths throughout the lungs.

(b) In some cases areas of necrosis are formed in the lungs, and in these suppuration proceeds apace and gangrene may supervene. The necrosis is often associated with, and appears to be caused by, septic thrombosis in the blood vessels, and for this perivascular lymphangitis may be held primarily responsible.

#### *2 Bronchiectasis*

This important occasional outcome of acute broncho-pneumonia is usually attributed either to the persistence of chronic smouldering inflammation in the bronchi which weakens their walls and leads to dilatation, or to fibrosis of the lung substance exercising traction upon them. Observations on certain cases among our series have served to throw some light upon the sequence of changes which results in bronchiectasis following acute broncho-pneumonia.

The earliest stages of the process are met with in cases of severe broncho-pneumonia, with purulent bronchitis and lymphangitis particularly well marked. The acute peribronchial lymphangitis with associated inflammation of the bronchial walls leads to complete destruction of the whole thickness of the wall in a part or the whole of the circumference of the bronchus. The destruction may extend to and involve some neighbouring alveoli. The result is the formation of a cavity whose lumen is surrounded by exposed alveoli, which are likely to be consolidated but are usually not in a state of suppuration. In fact, the cavity is often singularly clean-cut. Every vestige of the original structure of the bronchus wall—cartilage, muscle, elastic tissue—may disappear. If only a part of the circumference of the bronchus be affected, the rest of the wall remaining intact, the result is an irregular, somewhat sacculi enlargement of the lumen.

Later healing occurs in the walls of these cavities, by means of which a new bronchus wall is constituted. Granulation tissue springs from among the surrounding alveoli; the cavity comes to be enclosed by a layer of young fibrous tissue, epithelium surviving in neighbouring parts of the bronchus proliferates and clothes this fibrous wall with new epithelium, which is usually of a modified type, composed of low cubical cells. When the process of healing is complete the bronchus is reconstituted with a new wall composed entirely of fibrous tissue in which no remnant of the original structure is left.

If the initial acute process causes destruction of a considerable amount of tissue there will be, when healing is complete, an increase in the size of the lumen of affected bronchi—that is the end-result is bronchiectasis. The conclusion to be drawn from this is that bronchiectasis following acute broncho-pneumonia is not always the result of a slow smouldering inflammation which leads to gradual dilatation, but is sometimes an acute and active process of excavation, followed by the formation of a new fibrous wall around a lumen which has been enlarged by actual loss of tissue. Obviously the new fibrous wall must lack the strength conferred upon the normal bronchus wall by its muscle and elastic tissue. Therefore there is likely to follow a gradual progressive enlargement of the lumen by dilatation and even cases where there is at first no evident bronchiectasis are probably liable to develop it in course of time.

#### *3 Fibrosis of the Lungs*

I do not propose to consider those cases in which fibrosis originates in the pleura. There is a group in which fibrosis of the lungs occurs after broncho-pneumonia, independently of pleurisy. In some of them it may be simply the result of persistence in a chronic form of that inflammation of bronchial and alveolar walls which is so conspicuous in the acute stage of broncho-pneumonia. But in some at least, and perhaps in most, the underlying pathological process is apparently the same as that which has just been described leading to bronchiectasis. If the smaller bronchi be affected in this way the result is different from that in the case of the larger bronchi. For just as a small abscess is by healing converted into a fibrous scar, or a small plethral cavity closed by fibrosis, so a small bronchus whose wall is utterly destroyed may be obliterated by proliferation of granulation tissue in its lumen. The permanent obliteration of many small bronchi by this process must inevitably lead to permanent obliteration by fibrosis of large tracts of alveolar tissue.

We suggest that the pathological process underlying many cases of chronic pneumonia which go on to fibrosis and retraction of the lungs is thus obliterative bronchiolitis, which starts with wholesale destruction of the walls of small bronchi and ends with obliteration by fibrosis of the bronchioles and of the whole of their associated alveoli. As fibrosis of the lungs and bronchiectasis can thus be traced to a common source, it is to be expected that the two conditions will usually be present together. If, however, in any case the damage were confined to the small bronchi, fibrosis might result unaccompanied by bronchiectasis.

After this brief review it is evident that the extension of the inflammatory infection from bronchial lumen to surrounding lymphatics is the cause of the characteristic changes of both acute and chronic broncho-pneumonia.

We have still to explain why the infection in this form of pneumonia results in a massive invasion of the lymphatics. Of conditions which offer a possible explanation, the one most generally recognized is that broncho-pneumonia is often a sequel to some definite infective fever such as measles. In these cases there are two infections, and that of the primary fever is in some sense a preparation for the subsequent invasion of the pneumonia infection. The primary predisposes to the secondary infection.

On the other hand, it must also be recognized that in children broncho-pneumonia is often primary and without a preparatory antecedent infection. The infection settled in the bronchi simply invades the lymphatics; there is no obvious sequence of another infection. For the interpretation of these facts various suggestions have been offered, postulating separately or together (a) a virus of specific quality and possibly of special virulence also, and (b) a condition of the patient, non-infective and yet preparing the way for pneumonia. In favour of the latter suggestion is the fact that it still maintains, though in a new form, the general principle of predisposition in broncho-pneumonia.

The conditions advanced on this hypothesis are such as (1) age—less than 2 years, (2) bottle-feeding (3) under growth, (4) poverty, (5) lack of care in upbringing, (6) rickets.

Should it be shown that certain forms of virus have a special relation to broncho-pneumonia of the primary type, it will probably nevertheless be found that these conditions are still predisposing in their effect.

The importance of the consideration of predisposition as an etiological factor is that, should the hypothesis be proved, it would follow as a general conclusion that the elimination of broncho-pneumonia from the child community will depend to a corresponding extent on the application of preventive measures for the removal of the predisposing conditions.

#### DISCUSSION

Professor LEONARD DINDLEY (Glasgow) regarded age as the chief criterion in distinguishing between lobar and primary broncho-pneumonia in early childhood because he had hardly ever detected lobar pneumonia in necropsies on children under 3 years of age, he therefore considered all primary pneumonias in children under that age as examples of broncho-pneumonia. Of 65 consecutive fatal cases 55 were of primary pneumonia, and only one of these occurred in a child of over 3 years this case, in a child aged 5, was quite characteristic of lobar pneumonia. Fifteen of the 55 were typical clinically and pathologically of broncho-pneumonia. Fourteen were diagnosed before death as croupous pneumonia, but histologically were proved to be catarrhal in type. In 5 there was some difficulty in coming to a diagnosis, but ultimately 3 of these were regarded as examples of broncho-pneumonia, one was found to show a mixture of croupous and catarrhal features and one was diagnosed as probably lobar in type. Only one of the primary group of 55 was a typical example of lobar pneumonia, and this was in an older child. These findings differed from those in Dr Macgregor's series, in which there were 9 examples of lobar pneumonia in children under 2 years of age. In any case it is obvious that the prevailing type of pneumonia in infancy and early childhood was broncho-pneumonia and this owing to the tendency for the interstitial tissue of the lung to be involved in that type that bronchiectasis was so apt to follow. In searching for an explanation of the frequency of this special type at this age he was inclined to attach importance to a variation in the host rather than in the character of the infecting agent. There were several examples of an individual contagium vivum to which the tissues at different ages showed a varying reaction.

Dr J H THURSFIELD (London) reviewed the problem of treatment from the immunological standpoint and concluded that in all primary pneumonias in children the pneumococcus was the essential etiological organism. For treatment therefore it was not of great moment to come to a diagnosis as to the type of pneumonia present. During seven years he had had 126 cases of primary pneumonia under observation, 71 being in children under 2 years of age. Fifty-eight of these were treated symptomatically (mortality 41 per cent) and 13 with a sensitized vaccine prepared from several strains of pneumococci (mortality 30 per cent). Fifty-five were in children over 2 years. 41 of these were treated without vaccines (mortality 5 per cent), and 14 with vaccines (no deaths). The vaccine-treated cases were all particularly severe. He was convinced that he had seen several children recover from pneumonia when this vaccine was used who when first seen, had very little chance of survival. These results encouraged him to persevere with this method of treatment. He also referred to an apparently hopeless case of broncho-pneumonia in a child aged 2 in which recovery had ensued dramatically after immuno-transfusion.

Lieut.-Colonel W GLEN LISTON (Edinburgh) drew attention to the difficulties surrounding the study of the bacteria living in the respiratory passages. Many strains of pneumococci existed which, though morphologically similar, presented differences in virulence and in serological and cultural characters. The problem of determining the

cruse of pneumonia was, therefore, not a simple one, and called for some skill and experience in bacteriological technique. The post-mortem appearance of the lungs in the first cases he had seen with Dr McNeil had so strongly recalled to his mind what he had frequently seen during the severe outbreak of influenza in Bombay in 1918 that he had decided to make use of a special culture medium which he had found invaluable in the cultivation of the influenza bacillus. This medium had been prepared first by Dr Soparker at the Bombay Bacteriological Laboratory and was described in the *Indian Journal of Medical Research* (vol vi, No 3, p 418). With it he had obtained in many instances, on plates prepared from fluid removed from the congested areas of the lungs, almost pure cultures of the influenza bacillus. The organism was also readily obtained from the sputum. In 21 out of 55 necropsies on cases of suspected pneumonia influenza bacilli were isolated, all except 2 of the 21 cases were typical of primary broncho-pneumonia. One of the two exceptions was classed as a case of atypical lobar pneumonia, the exact type of pneumonia of the other case was not determined, the case was complicated with empyema and cerebro-spinal meningitis. Of the 21 cases from which influenza bacilli were isolated from the lungs the heart blood was sterile in 9. A pure culture of the influenza bacillus was obtained from the heart blood in 2 of the cases, and that bacillus was present together with other organisms in 3 other cases. In 3 cases a pure culture of streptococci, a pure culture of pneumococci and a pure culture of a staphylococcus were obtained respectively from the heart blood. No culture was made from the heart in the 4 remaining cases. The 12 cases from which the influenza bacillus was not recovered were 2 cases of tubercle of the lungs, 2 cases of pneumococcus meningitis, 1 case of meningococcus meningitis, 1 case of bronchitis, 1 case of organized pleurisy showing very little pneumonia (probably a late case of broncho-pneumonia), 2 cases of septic broncho-pneumonia, 1 case of lobar pneumonia and 2 cases of primary broncho-pneumonia. In 22 examinations made of the throat in children, influenza bacilli were isolated from 6 cases, 3 of these were clinically regarded as suffering from broncho-pneumonia, 2 from lobar pneumonia, and 1 had been admitted to hospital with rickets. The 16 negative swabs were obtained from 4 cases of broncho-pneumonia, 5 cases of lobar pneumonia, 2 cases of pneumonia of undetermined type, 2 cases of bronchitis, one case of asthma, one case of ecchyma vomiting and one case of marasmus. The influenza bacillus appeared to be specially prone to attack young persons causing in them very definite lesions even in the absence of other organisms, in some way it opened a path for the invasion of the body by other organisms such as streptococci, pneumococci, and staphylococci. The high death rate from broncho-pneumonia in children was attributable to the influenza bacillus, but the organism could be obtained from patients who recovered. Much work remained to be done in determining the characters of different strains of this bacillus and its distinction from allied organisms such as that of whooping-cough and the Koch Weeks bacillus.

Dr N S CAMPBELL (Edinburgh) held that it was important to differentiate sharply primary or lobular and secondary or interstitial pneumonia. The diagnosis of the latter type as a rule was easy, the mode of onset, the associated catarrhal symptoms and signs and the course of the illness were characteristic and the infection, it was generally agreed, was a mixed one. In the much smaller group of primary broncho-pneumonia the onset was sudden, consolidation appeared early and the temperature fell by crisis or rapidly. The resemblance to lobar pneumonia was therefore close and it was often impossible to separate the two conditions, the organism responsible was the pneumococcus but other such as Pfeiffer's bacillus were sometimes also present. Was it not possible that this form of primary pneumonia was the infantile expression of lobar pneumonia. In older children the pneumococcus gave rise to distinct types of pneumonia cerebral and abdominal which could not be explained by structural effects. Might not different strains of the pneumococcus have each its own special train of clinical

manifestations? He considered that it was along bacteriological and serological lines that knowledge of pneumonia would advance.

Dr C P LANGE (Manchester) referred to the hypothesis that during the course of the disease there might be a change of type from lobar pneumonia to broncho-pneumonia. Hospital statistics could be misleading, because, even in infants, most cases of lobar pneumonia did not come to hospital. Clinical investigation should be made, not only of hospital cases, but also of those treated at home, for this the collaboration of general practitioners would be necessary. It was usually possible by a study of symptoms and physical signs to distinguish lobar pneumonia from broncho-pneumonia, and in most cases to base a prognosis on these data and on the condition of the infant. It was his firm opinion that acute lobar pneumonia occurred in infants, and that the prognosis was usually good. Repeated radiological observations might throw light on the problem of type. The nature and course of an attack of pneumonia were determined partly by variable elements and partly by predisposition. Variable elements, such as a chance mixture of infections, might affect the route of spread of the infective process and alter the character and course of the illness. Predisposition was important in relation to factors lowering the vitality. Thus diet, especially the use of unsuitable infant foods, played a prominent part in the lowering of resistance. Debilitating disease was also a factor in determining the nature of an attack, the liability of infants with rickets and "pink disease" to develop broncho-pneumonia was well known.

Dr P F ARMAND DELILLE (Paris) drew attention to the value of fluoroscopic examination as a diagnostic procedure in acute pneumonia in infants. Lobar pneumonia produced a very definite triangular shadow, whereas broncho-pneumonia gave no characteristic picture. Fluoroscopy was often the only means of clearing up the diagnosis in those cases of lobar pneumonia in infants in which there were no signs detectable by the stethoscope. In other acute respiratory cases the absence of a characteristic shadow would substantiate the diagnosis of broncho-pneumonia and be of prognostic value.

Dr H C CAMERON (London) thought that the discussion had made it clear that clinicians differed as to the value and even the possibility of distinguishing during life between lobar pneumonia and broncho-pneumonia in infants. The lobar pneumonia mortality increased steadily from early childhood, but in the first two years of life the fluid was lost in a great number of examples of broncho-pneumonia characteristic of that age. He believed that Dr Armand-Delille and Dr Lange were right in emphasizing the occurrence of typical cases of lobar pneumonia in the first two years of life. The presence of delirium was characteristic of the lobar form, as was often the appearance of dullness at an early stage, in broncho-pneumonia dullness was the last sign to appear.

Dr A G NEWELL (Haringey) referred to a paper he had read about two years previously at a meeting of the North Middlesex Division, in which he had advocated the value of vaccine treatment in pneumonia. He strongly recommended every general practitioner to try it. In his experience the clinical picture changed in a striking way within forty-eight hours of the first injection.

Dr C W VINEY (Leeds) had no doubt that there were two clinically different classes of pneumonia in early childhood, one termed lobar pneumonia, with a short course and good prognosis, and one called broncho-pneumonia, with a more lengthy course and doubtful prognosis. He suggested that empyema occurred much more frequently in the lobar type than in broncho-pneumonia, this was indicated by the infrequent development of empyema during the course of measles and whooping-cough. He was impressed by the value, even in the youngest child, of open-air and balcony treatment in broncho-pneumonia. He protested against large quantities

of milk being given to small children during an acute illness. He thought also that the continuous administration of oxygen by means of a small nasal catheter was most useful. Hitherto he had seen nothing to convince him that anything was gained by using serums and vaccines in these cases, but he now proposed to try a sensitized polyvalent pneumococcal vaccine.

Dr F M GARDNER-MEDWIN (St Asaph) advocated the injection of sodium nucleinate combined with glucose and sodium bicarbonate in pneumonia. Details of the method were published in the *BRITISH MEDICAL JOURNAL* in 1923 (vol 11, p 49). His experience was that this method was of the greatest service in curtailing the pneumonic attack and improving the general condition in children as well as in adults. In lobar pneumonia the crisis was brought about almost invariably within forty-eight hours of the administration of 2 ccm of the solution prepared by the Clinical Laboratories of Paris. In broncho-pneumonia the change was not so dramatic, but the condition of the patient was improved in nearly every case. Forty consecutive patients with lobar pneumonia treated with nuclein and intensive alkalization during the influenza epidemic of 1918-19 had responded within forty-eight hours, irrespective of the duration of the illness. Since then his results had served to confirm his former estimate of the value of this agent in inducing a leucocytosis in all cases except those in which bone-marrow response was interfered with by antecedent pathological conditions, and thus reinforcing the natural defences of the body. With regard to the suggestion that Pfeiffer's bacillus was responsible for the lowered resistance which allowed invasion by the pneumococcus, Dr Gardner-Medwin added that if a leucopenia was also observed in these cases the argument for using the nucleinate treatment was very strong.

Dr S P HUGGINS (High Wycombe) referred to the case of a child with pneumonia who had been treated with small doses of pneumococcal vaccine, and who later developed empyema. The fluid was found to be sterile, and complete recovery followed. The administration of oxygen by subcutaneous injection had been advocated on the Continent.

Dr WILKIE SCOTT (Nottingham) suggested that a classification based upon either mortality or morbid anatomy would show a very much smaller proportion of cases of lobar pneumonia than one based upon clinical evidence, since lobar pneumonia was mostly fatal by reason of complications. Clinically lobar pneumonia was common in children. Insufficient stress had been laid on the fact that lobar pneumonia was an acute specific fever, and that the local lesion in the lung bulked less largely in the picture than in broncho-pneumonia. Vaccine treatment might be worth while if begun within the first three days of the attack, in which period it was free from risk. In one case a massive dose of 10,000 million pneumococci, streptococci, and influenza bacilli was accidentally given to a patient on the second day of an attack of lobar pneumonia, with the only effect that the temperature fell to normal on the next day, and there was a corresponding improvement in the patient's symptoms. While many cases of lobar pneumonia untreated by vaccines were of very short duration, the occurrence of the abortive type appeared to be more frequent over a large series of cases treated by vaccines. He had tried the subcutaneous injection of oxygen in seven cases of pneumonia, but had not been convinced that this method had any special merit. He had also given sodium nucleinate, but had not obtained improved results.

Dr HELEN MICKLE (London) said that if the incidence of diseases of the upper respiratory tract, which were so prevalent amongst city children of the working class, could be lessened, there was little doubt that the incidence of broncho-pneumonia would also fall. Some years ago she had realized the close association between respiratory disease and an inadequate supply of vitamin D in the diet, and the possibility of lessening the frequency of catarrhal conditions by the administration of cod liver oil in the winter. There were under observation in Vienna at that time two groups of infants, one of which received cod liver

oil. The difference in the frequency of respiratory infections in the two groups was very striking during the winter, but during the summer, when all the children were much out of doors, vitamin D consequently being produced in the patients' own tissues there was little difference between the susceptibility to catarrhal infections of the two groups.

The President felt that the high mortality of pneumonia in young children did not redound to the credit of the profession, and that more active measures were necessary. He strongly recommended immunisation as a method of treatment in urgent cases of infective disease.

## THE HISTORICAL ASPECT OF QUACKERY \*

BY

A. J. CLARK, M.D. F.R.C.P.

Professor of Pharmacology, University of Edinburgh

THE term quack simply means one who pretends to knowledge or skill that he does not possess, and the fact that this term has come to signify in popular usage a pretender to medical knowledge indicates very clearly that there is something about the cure of disease that particularly attracts both delusion and imposture.

The quacks who prey upon human suffering are actuated by a variety of motives the simplest of which is frank greed, and to it we owe the semi-permanent commercialized quackery of so-called patent medicines. Among the ordinary quack medicines are sensational examples of the utter carelessness and recklessness of those who seek to exploit human suffering for gain and also remarkable evidence regarding the unlimited gullibility of the general public, but these traits are exhibited in many other fields of human activity and therefore have no specific interest to students of medical history. There are, however, other aspects of quackery which I believe deserve the attention of medical historians, not because their study throws any light on the history of the development of medical science, but because it provides evidence regarding the reaction of the popular mind to the spread of this science.

The question that I wish to consider is very general, public so often turns away from the medical profession and follows quacks who pretend to the possession of cures unknown to medical science. Such pretenders usually claim direct personal inspiration and in consequence assert complete independence of medical science. The nature of the cures is so varied as to defy classification, but usually their freedom from the fetters of science causes them to be cures applicable to all diseases.

Prior to the seventeenth century the occurrence of such revolts from official medicine was not surprising for orthodox medicine was based not on experimental science but on the authority of Galen, and the recognition of any infallible authority naturally arouses the opposition of all those who wish to think for themselves. Many revolts of this nature led to valuable results because they favoured the testing of the tenacity of dogmas held to be infallible. The career of Hahnemann, however, is a striking example of the way in which a rebel against authority who commences with an appeal to reason may finish by establishing a dogmatic faith even more absurd than the orthodox traditions he tried to explode.

Prior to the nineteenth century the quack might claim that he was merely asserting the authority of his ideas against the weight of tradition, but during the nineteenth century medicine has broken away from tradition and to-day claims to be an applied art based on experimental science. This change has been accompanied by an unprecedented increase in the efficacy of medical methods and hence to-day the quack challenges not tradition but the findings of experimental science.

Another outstanding feature of the nineteenth century was the spread of popular education and many imagined that this alone would be fatal to quackery. The fallacy of this belief is, however, well illustrated by the experience of the medical profession in Germany. The laws of Prussia

forbade the practice of medicine by unqualified persons but in 1869 general liberty to practise was granted. This change was indeed supported by the physicians partly on the ground that the repressive legislation was ineffective, but also partly because it was believed that the spread of popular education would safeguard the people from being deceived by quacks. The number of quacks in Germany is known because they are required to register and their number has steadily increased until to-day the proportion in Berlin between quacks and medical men is one to three and a half, the proportion throughout the whole of Prussia is nearly one to four.

In consequence the German medical profession is now agitating to induce the Government to protect the health of the people by restricting the activity of quacks. Since Prussia is one of the best educated nations in Europe I think this is a very striking evidence of the fact that the spread of education does not influence the popularity of quackery, although it may influence the form which it assumes.

The activities of the quacks therefore have not been checked by the dramatic successes of medicine nor by the spread of popular education. At the same time there is a considerable amount of evidence to indicate that while the medical profession has become more scientific and more successful it has also become increasingly unpopular with the masses. The last century has seen the development of numerous popular agitations against medical science, such for example, as the antivaccination and antivivisection movements, and there is no evidence that the popularity of these causes is decreasing. This opposition is not confined to the uneducated but finds its leaders amongst those who claim to be pioneers of advanced thought.

The present situation is indeed rather curious, for while medical science has advanced from triumph to triumph and is ever now steadily increasing its powers to combat and control disease, yet a large section of the population appears to regard the profession with distrust and to turn eagerly to any charlatan, however ignorant, who claims to claim that he possesses special or supernatural powers of healing.

A consideration of the careers of the outstanding charlatans furnishes some clue to the factors upon which their success has depended. The common type is that of a man of unusual force of personality who in virtue of an imperfect education and ill-balanced judgement has acquired the profound belief that some direct inspiration has made him independent of the slow advance of science and has endowed him with semi-miraculous powers of healing. The list of these persons is long. A hundred years ago Perkins persuaded millions that all disease could be cured by stroking the body with two pencils of metal while to-day the followers of Abrams believe that all diseases can be both diagnosed and treated by means of two boxes containing some simple electrical apparatus.

In addition to the cures that achieve a fame there are of course an indefinite number that fail to catch the public fancy, and it is puzzling to know what are the factors that cause success, for often the failures appear to be much more ingenious and attractive than the successes. The reason appears to be that reason is not involved in the process but that the initial success depends on the personality of the healer and subsequent success is ensured by mass suggestion. The reason for the successes is that these mysterious cures provide what the public want for they furnish an escape from science and a line of retreat back to the old primitive beliefs of the cave man. The facts regarding the fundamental beliefs of mankind have been summarized by Sir James Frazer.<sup>1</sup>

When we survey the existing races of mankind from Greenland to Tierra del Fuego or from Scotland to Singapore we observe that they are distinguished one from the other by a great variety of religion. When we have penetrated through these differences which affect mainly the intelligent thoughtful part of the community we shall find underlying them all a old statement of intellectual agreement among the dull the weak the ignorant the vast majority of mankind. This universal faith this truly catholic creed is a belief in the efficacy of magic. Among the ignorant and superstitious classes of modern Europe it is very much what it was thousands of years ago in Egypt and India and what it now is among the lowest savages surviving in the remotest corners of the world.

\* Read in the Section of the History of Medicine at the Annual Meeting of the British Medical Association, Edinburgh 1927.

<sup>1</sup> The Golden Bough. Abridged edition 1925 p. 55.

It is in this universal and eternal creed that the Christian finds his support. In a civilized community the belief in magic is concealed beneath the veneer of education and does not obtrude itself in normal life, but the veneer cracks as soon as any strong emotion is aroused, and both pain and fear of death are potent causes for arousing such emotions. The exaltations of science are utterly antipathetic to the sick person, who resents being regarded as a "case" for whom the chances of recovery are so many per thousand. The more intelligent turn to religion and to spiritual healers to appeal to some higher power to intervene on their behalf and set aside the soulless laws of nature that are threatening their safety.

The less intelligent revert to the oldest form of belief and seek someone who will make strong magic for them and defeat the evil spirits by some potent charm. This is the feeling to which the quack appeals, he claims to be above the laws of science and to possess some charm for defeating disease of any variety.

The nature of the charm changes with the growth of education. A naked nigger howling to the beat of a tom-tom does not impress a European, and most modern Europeans would be either amused or disgusted by the Black Mass that was popular in the seventeenth century. To-day some variety of physical science appears to be the most popular form of incantation. But although the form is changeable yet the underlying belief is unchanging and ineradicable, and I think that the medical profession must face the fact that, although their alliance with science has brought them great material success, yet it has brought its special penalty in that it is ever alienating them to an increasing degree from the fundamental beliefs of the common man.

## THE TREATMENT OF BURNS

BY

ALEXANDER MACLENNAN, M.B., C.M.,  
Honorary Consulting Surgeon to the Royal Infirmary, Stirling,  
and to Falkirk Infirmary

It is highly advisable from time to time to review our doctrines on treatment, even the most orthodox. We must be ever on the watch for discoveries in collateral science which may be applicable to our own. Many conundrums are waiting for their solution the preliminary discovery—Pain must precede Lister. In the case of burns we are confronted by several problems.

### Pain

Anyone who has been at all severely burned will at once assert that the only problem in burns is the relief of pain, and that in the quickest possible time. I readily agree that it is the most important part of the subject. If this were the only item to be dealt with there would be no difficulty, but our remedies to ensure immediate mitigation of the disaster must not endanger the future for the victim. Fortunately the perception of pain is limited by exhaustion of the nerve centres, and most of those fatally burned are ominously comfortable during the brief interval between the accident and death.

Children are peculiarly susceptible to injury from burns, and most of us have been shocked by an unexpected fatality from a trivial burn. The much disputed status of hamphlets (in the absence of more precise knowledge) brings an otherwise unwarmed death into line with other injuries. The resistance to toxæmia is in those cases much lowered, the fatty degeneration of the liver frequently found at the necropsy may have some bearing on the fatal issue.

For the majority of patients who recover extensive resort to sedatives is necessary, and it is of great importance that their remote general effects be closely watched. I might suggest that the prolonged administration of chloroform, not as an anæsthetic but as an anodyne, may be less toxic and dangerous than the corresponding amount of morphine. The inhibition of a diluted vapour may be allowed for long periods, and may be safely carried out by a trustworthy nurse.

The surgeon's visit to a ward containing the victims of burning is evidently a time of trial to the patients, they

clamour for chloroform, morphine, and death. I know of no condition which occasions such an accumulation of suffering in a single ward. The remedies we employ will require to be many-sided, more than one effect being demanded. For example, while a remedy may be soothing, it must not encourage suppuration or discharge. In exceptional instances an extensive burn is tided over the period of initial shock, and the subsequent treatment becomes daily more onerous. For these patients the continuous bath, where circumstances will permit, is a satisfactory plan, unfortunately in only a few cases can it be made available. Next to the principle of relieving the pain, the exact nature of the first dressing is of importance. Where bullæ are present it is not my practice to drain them, the effused serum being the best covering possible, when they show signs of pus formation they should be emptied. Spraying the area involved with a solution and covering it with an oily and bland substance are procedures which have rightly found a lasting place in treatment. I would suggest the value of covering the scorching surface with waxed paper, angles may be cut to allow of the discharge reaching the dressing. Such waxed paper may be sterilized without detriment. A thick tissue paper soaked in eucalyptic oil may be also similarly used.

There are few cases where good nursing is more rewarded, extreme gentleness in handling is demanded, and the raw surface should never be wiped with gauze, any discharge being washed off. I firmly believe that the pain associated with a burn, in all but the final stage, is the cause of most of the trouble met with, hence applications which relieve pain will give better results, even remotely. Thus alcohol has achieved some reputation as a suitable application, its effects are not due to its antiseptic action, but to its anæsthetic action on the nerve endings and to its dehydrating properties. The possible precipitating effect on toxins can be ignored. In picric acid we have another remedy which is very effective, not altogether because it is an antiseptic, but because it is an analgesic, and also because it coagulates albumin. By thus causing the production of a layer of sterile albumin which is at the same time emitting analgesic properties a very good effect is produced. Picric acid is one of the scheduled explosives, and can only be procured in solution or in gauze. It may be applied in a saturated solution, but should not be spread too extensively because of its own poisoning properties. Toxicity may be recognized by the onset of fever, accompanied by a rise in pulse rate and the production of a widespread itchy miliary rash. The urine becomes green tinted as in carbolic acid, and there is much general distress. After mitigating the pain future contingencies must be considered.

### Shock

The treatment of this accompanying condition should be conducted along recognized lines. Repeated small doses of opium or morphine with oral administration of alcohol should be given. If alcohol is being extensively applied as a dressing some will be absorbed, so it need not be given otherwise. In a burn the central nervous system is stimulated to the point of exhaustion, and there is no want of explanations for many of the associated phenomena.

### The Body Fluids

It has been shown that the blood tends to become—first at any rate—concentrated and less alkaline, as well as to contain more waste products. The symptoms have been explained as being largely due to absorption of substances produced in the tissues by the destructive action of the heat, but this cannot be merely a chemical reaction. Some time ago in attempting to get protein shock I injected the products of partial destruction by heat of animal tissues, but neither intravenous nor intracellular injection caused the slightest effect. It is also affirmed that the chlorides are reduced as in pneumonia, and indeed in many other diseases. A diminution in the chlorides is usually associated with an alkalosis. From whichever point of view the subject the essential treatment, whether acidosis or alkalosis be present, is the administration of fluid, this may be loaded with alkalis or sodium chloride. I do not think it matters which—provided we introduce fluids into the circulation.

\* Read in the Section of Surgery at the Annual Meeting of the British Medical Association, Edinburgh, 1927.

### Sepsis

Some degree of sepsis is inevitable. The damaged surface is less able to resist either a fresh invasion or the growth of organisms unscathed by the heat. Powerful antiseptics cannot be applied, nor can weak ones be frequently used. In many cases the attempt to apply a theory may do more harm than good; hence digressions from established authority should be very carefully introduced. I know of no better antiseptic for a burned surface than normal sheep's or horse's serum; the cost is its only drawback. Pneumonia, which accounts for many of the deaths after burns, is probably a manifestation of sepsis, and is produced by a septic embolism.

### Duodenal Ulcer

This is in my experience, incidentally rarer among the burned than among those not so affected. I have never seen one case in patients suffering from burns. It is more the figment of the imagination of the student going in for an examination.

### Surgical Intervention

In many cases we do not apply the principles of surgery early enough. At first burned patients are unable to sustain further wound into their vitality, and later on it is sometimes forgotten that surgery may improve the outlook both as regards immediate morbidity and ultimate appearance. Where a limb has been almost denuded of skin only amputation is indicated. Short of this it will be found in many cases—and this is the experience of most of us—that an ulcer produced by surgery is much less severe than one resulting from a burn. It is the uncertainty of our judgement regarding the vitality of the section of burned surface which makes us hesitate to resort to extensive excision. It is often surprising how many islets of epithelium appear among the granulations after the slough of what we considered to be the entire thickness of skin has separated. Even though we may finally have larger areas to epithelialize than would have formed without excision we certainly lessen suffering very materially. I think the tendency hitherto has been conservative. Simultaneously with the excision provision should be made for grafting. Large ulcers are to be treated upon general lines; the longer they remain the greater will be the tendency for contractures to occur. On the other hand acquiescing in the production of a contracture may result in a rapid obliteration of the ulcer, yet such a contracture should not be allowed to develop, but the ulcer should be healed by other means.

### Grafting

Successful grafting requires careful preparation of the field; indeed until the septic process has ended grafting should not be undertaken if the Thiersch or Wolff method be adopted. Many years ago I introduced a method of grafting to which the name of 'tunnel grafting' was given; it can be applied at an earlier stage than any other and has a high percentage of successes. Narrow grafts are embedded under the surface and their locality marked by lying alongside them suture threads. After allowing for their taking root, which occurs in about ten days the covering surface is removed so as to expose the grafts completely. On account of the close resemblance of the granulation tissue developed to sarcomatous tissue in its destructive effects a thin epithelial covering is almost certain of being destroyed from time to time. This feature of constantly recurring ulceration must be familiar to all; hence a solid covering is essential if healing is to be permanent. It is interesting to note that if embedded grafts are left for any length of time under or in the granulations they entirely disappear. This is a usual phenomenon; otherwise operation implantation grafts would be commoner.

As an aid to the spread of epithelium scarlet-red applied in an ointment is a very decided stimulant. Where serious grafting is required the pedicled graft is best; it is often noticeable that sepsis tends, when these grafts are freed to light up the process of ulceration. The development sometime is the cause of failure in grafting for the relief of contracture even in cases long since healed. It would

seem that cicatricial tissue is capable of retaining encysted within its meshes, infection in an active state. The development of keloid is one evidence of such a power.

In considering burns generally we nearly always have in our minds the effects of heat, yet cold chemicals, ultra-violet rays in sunlight direct or reflected from snow or those produced electrically, induce similar disturbances. Another form of burn fortunately now less common, is that produced by radium and x-rays. Burns so caused show great resistance to healing and their tendency to become malignant is well recognized. Occasionally when an ordinary burn has been allowed to pass into a chronic ulcer malignancy may become engendered.

### DISCUSSION

Mr W. C. WILSON (Edinburgh) gave his experiences with tannic acid in the treatment of 37 cases of burns in children. He said that at the stage of initial shock tannic acid was beneficial in that it promoted a rapid and complete analgesia. In the stage of acute toxæmia the main indication was to prevent absorption of the toxin, in this respect the action of tannic acid was striking and valuable for by coagulating the tissue at the burnt area it prevented absorption of toxin into the blood stream. In the stage of septic toxæmia tannic acid by providing a firm, dry covering to the wound minimized the incidence of sepsis; it also protected the growing epithelium and promoted rapid healing. Primary shock was treated in the usual way—a small dose of morphine being given if necessary. No general anaesthesia was employed. The burnt areas were cleansed rapidly with ether. A freshly prepared solution of 2½ per cent. of tannic acid in warm sterile water was sprayed over the burnt areas at intervals of an hour and the application was dried by electrical heat. This was continued until a brownish black coagulum formed (eight to twelve times). The bed clothes were eradicated and the parts exposed to the air during this time and until the coagulum was removed. While spraying the face, the eyes, ears, and nostrils must be protected. Slides were shown to illustrate the effect of treatment on mortality, the prevention of acute toxæmia, and the improvement in prognosis thus obtained.

Mr STEWARD (London) agreed that tannic acid gave excellent results. He preferred to make a careful toilet under anaesthesia at the beginning of treatment.

Mr R. M. MANNING WHITE (Northwich) said that the three essentials of relief in burn treatment of shock and prevention of sepsis were obtained by using the pomade of Reclus which contained phenazone, salol, boric acid, iodolorm, phenol, mercury perchloride and vaseline.

## A CASE OF ABNORMAL FAT METABOLISM

BY

JAMES A. TORRENS, M.D., F.R.C.P.,

PHYSICIAN, ST. GEORGE'S HOSPITAL.

H. GAINSBOROUGH, M.B., M.R.C.P.,

ASSISTANT PHYSICIAN, ST. GEORGE'S HOSPITAL.

AND

J. A. GARDNER, M.A.,

FELLEW IN PHYSIOLOGICAL CHEMISTRY, UNIVERSITY OF LONDON.

THE clinical symptoms in the following unusual case suggested some defect in fat metabolism and in the hope of ascertaining its nature a thorough investigation was made; the results though they did not explain the mystery seem worthy of record.

A girl aged 15 was sent to hospital because her mother had noticed progressive loss of weight for two years; she had not seemed ill, her appetite was uniformly good, her bowels were open naturally, and she was quite ordinarily energetic though during the last few months she had been apt to tire easily. The mother had given the child various tonics, and had persistently tried to feed her up with cream, milk, and cod-liver oil; these extra fatty foods were taken readily and with aversion was born to any particular foodstuff. Menstruation had not started. There had been no previous illness of note.

When admitted, on December 15th, 1926 she was a small, bright, fresh complexioned, alert child, weighing 47½ lb (the normal weight for a girl of 13 is 87 lb), lips and skin rather dry, tongue clean and moist, teeth good. The heart, lungs, abdomen, and central nervous system were all normal. With the exception of the face, which appeared normal, there was throughout the entire body an almost complete absence of all subcutaneous fat, the muscles standing out under the skin as in wasting disease. This was more noticeable in the arms, thorax, and abdomen than in the legs. The muscular power was unimpaired. The urine was normal as were the stools, both to the naked eye and to microscopical and cultural examination. Clinically it seemed probable that there was some defect in fat metabolism and it was decided to try a diet in which the fat content should be materially reduced, the effect was dramatic, as is shown on the accompanying graph.

The sudden temporary drop in weight on January 27th was due to polyuria following a sugar tolerance test.

From a study of the child's weight in relation to the diet it soon became clear that on an ordinary mixed diet the weight slowly but steadily decreased, but that when the fat intake was restricted (by no means completely) there was a rapid gain in weight, amounting in one period of twenty-five days to 14 lb 6 oz, and in a later period of ten days to 2 lb 3 oz. From the clinical findings it was very difficult to suggest any hypothesis to explain these facts, so certain investigations were made to see if any light could be thrown on the cause of the abnormal metabolism. The following figures were obtained.

December 22nd (fat restricted diet) Blood sugar 0.0798 (Shaffer-Huitman) Plasma cholesterol free, 0.04904 per cent, ester 0.07224 per cent, total, 0.1213 per cent. Percentage of total as ester, 59.8. Total solids of plasma, 9.338 per cent.

January 26th (fat restricted diet) Glucose (25 grams) was administered and the sugar tolerance test performed. This showed blood sugar, 0.104, after half an hour, 0.126, after one hour, 0.155, after one and a half hours, 0.150, after two hours, 0.102, after two and a half hours, 0.093.

January 27th Urine analysis Volume in twenty-four hours, 1,095 c.c.m., specific gravity 1.0167, total nitrogen, 0.84 per cent, free ammonia, 0.032 per cent, urea, 1.325 per cent. Sulphur excretion was as follows:

	Grams per day	Normal for adult per day
Inorganic, as SO <sub>4</sub> , 0.103%	1.1865	—
Ethereal, " 0.0171%	0.1873	0.2 gm
Neutral, " 0.0295%	0.3233	0.2 gm
Total	1.6971	1.3 gm

Total N/total SO = 5.32, normal = 5

The analysis of the urine was made on the day following the sugar tolerance test, the twenty-four hour volume being as stated. The average daily volume was about 600 c.c.m.

The respiratory quotient was also determined during the period of restricted diet, at intervals after a meal consisting of 4 oz of meat, 2 oz of greens, 3 oz of potatoes, 1/2 oz of bread, 4 oz of tapioca pudding, and a glass of water. The respiratory quotient was determined on ten minutes samples of expired air, using a Douglas bag. The patient was quiet throughout the experiment and breathing normally. The meal was taken at 11.45 a.m. At 2 p.m. the respiratory quotient was 0.87, at 2.30 p.m. it was 0.87, and at 3 p.m. it was 0.86.

Fat balance experiments were also made over two periods of three days each. In the first period (December 17th to 19th inclusive) the diet was restricted as regards fats by omission of butter and eggs and by using lean meat. In the second period (January 17th to 19th inclusive) the patient had an ordinary diet including 2 oz of butter, 4 oz of milk, milk pudding, and one egg. On each occasion the same diet had been given for a few days previously and was carefully measured. Duplicate diets were collected throughout and also the faeces during the seventy-two-hour periods.

The whole of the food with the exception of the fluids and the butter, which were separately estimated, was dried and ground in a mill and a portion of the thoroughly mixed meals so obtained was analysed. The sterol balance was also determined. During the second period on the non-restricted diet, a nitrogen balance was also ascertained by analysis of the faeces and urine. The results were as follows:

Fat-restricted Diet (December 17th to 19th)		Fatty Diet (January 17th to 19th)
<b>Fat Balance</b>		
Fat intake	176.475 gm	241.86 gm
Fat output in faeces— 1st and fatty acids Soaps	2.929 0.693 } 3.619 gm	19.89 0.69 } 20.58 gm
Fat absorbed in three days	172.856 gm	221.16 gm
Fat absorbed in one day	57.618	73.70
Utilization of fat	98 per cent	91.56 per cent
<b>Composition of faeces—</b>		
Total other extract	2.929 gm	19.89 gm
Free fatty acid as palmitic	1.31	4.01
Unsaponifiable matter	1.593	1.91
Neutral fat	0.035	14.91
<b>Sterol Balance</b>		
Intake of sterol	1.1734 gm	1.1685 gm
Output of sterol	0.6152	1.0938
Difference	+0.5582 gm	+0.0147 gm
Difference per day	+0.186	+0.049
<b>Nitrogen Balance</b>		
Intake of food	—	20.78 gm
Output in urine	—	25.77 gm
Output in faeces	—	3.61 gm
Difference	—	-0.60 gm
Difference in one day	—	-0.23

### Comment

These investigations on the whole yielded normal figures. The blood sugar, total solids, and cholesterol of plasma were normal, as also were the respiratory quotients. One noteworthy figure was the high value for neutral sulphur in the urine, which is generally considered an expression of the endogenous protein metabolism.

The nitrogen balance during the unrestricted diet period showed an insignificant increase of output over intake, corresponding in direction with a slight loss in weight during that period.

The fat balances were interesting inasmuch as they showed the completeness of the fat splitting and the fat absorption from the alimentary canal. The sterol balances show a remarkable agreement with the change of the patient's weight in the two experimental periods. During the first period the excess of intake over the output was 0.186 gram per day. The gain in the patient's weight at this time averaged 307 grams a day, and if we take an average figure of 0.06 per cent for the sterol content of body tissues this would correspond to a utilization of 0.184 gram. During the second period, when there was a very slight loss of weight, the sterol balance was almost exact, the actual figure for the difference of intake and output being within the limits of experimental error.

It is very difficult to draw any conclusions as to the nature of the anomalous metabolism. Clearly the error was not one of intestinal malabsorption of fat. The clinical improvement was dependent on only a moderate restriction of fat intake from 80 grams a day to 59 grams. The respiratory quotient, determined after a mixed meal, and the evidence relating to the carbohydrate metabolism threw no light on the mystery. In the use of the two diets, in one case approximately 58 grams of fat was absorbed a day and in the other 74 grams. This latter certainly represents an unnecessarily high fat intake, but does not correspond to such marked increase of the fat to carbohydrate ratio as to suggest any failure in the efficient metabolism of fat from this cause. Acetone bodies were never found in the urine, and the glucose tolerance was quite normal.

It is to be remembered that when the observations were commenced the child was markedly under weight and the restriction in the fat intake allowed her to become more nearly normal. At a later date the ingestion of a fatty diet again caused loss of weight and appeared to act as metabolic poison. This excess of fat was well absorbed, and throughout the experiments there was no failure of alimentary function. From our evidence it seems impossible to explain why a high fat intake should interfere with the normal deposition and storage of fat in the body tissues.

## A STUDY OF EPHEDRINE

BY

K K CHEN, PH.D.

(From the Laboratory of Pharmacology, Peking Union Medical College, Peking, China)

Ma Hsing has been identified as *Ephedra vulgaris*, var. *helicifera*. It is a low dioecious practically leafless shrub, 60 to 90 cm high. The stem which is green, ribbed, and channelled is the part sold in Chinese drug stores. It is usually cut into pieces, 1 to 1.5 cm long. Ephedrine, a natural secondary amine, is the physiologically active constituent and can be easily isolated from the plant by immiscible solvents. It was first discovered by Nagai in 1889 and its structural formula has been studied by different observers.

## The Action of Ephedrine

Our preliminary reports have shown that ephedrine possesses sympathomimetic actions and that its outstanding feature is its circulatory stimulation.

(a) *On Circulation*—An intravenous injection of ephedrine in an anaesthetized dog or cat always results in rise in blood pressure and increase in pulse rate for fifteen or more minutes. The site of action is not in the central nervous system for destruction of brain and cord does not prevent the rise in pressure. The acceleration of pulse is not due to depression of the parasympathetic system for atropinized animals respond just as well as non-atropinized, and in fact, the pulse is usually decreased in non-anaesthetized animals. Unlike adrenaline the rise in pressure is not due to peripheral constriction, for intestinal and kidney volumes are often passively increased. Application of the drug directly to the stellate ganglia causes a marked increase in rate and strength of cardiac contractions, but only little rise in blood pressure. When ephedrine has produced maximal cardiac stimulation by local application to the stellate ganglia, or when the latter are paralyzed by intravenous injection of nicotine, ephedrine given intravenously still elevates the blood pressure in the usual manner. It appears clear that the rise in blood pressure is mainly due to the stimulation of structures peripheral to the sympathetic accelerator ganglia—sympathetic junction or the muscle itself. Since ephedrine acts on the nervous structures of other muscular organs it is probable that it does the same thing here.

(b) *On Smooth Muscles*—The action of ephedrine on smooth muscles follows very closely the sympathetic innervation. Thus the pupils are dilated by the application of ephedrine to the conjunctival sac. The light reflex is retained and physostigmine causes prompt miosis. Bronchial spasm due to physostigmine is rapidly relieved by ephedrine. The isolated gut is inhibited and relaxed, the vessels of the perfused kidney show definite and prolonged constriction and strips of rabbit's uterus suspended in Tyrode's or Locke's solution undergo one or more powerful contractions when ephedrine is added. The site of action is apparently only concerned with the terminal nervous structures for direct application of ephedrine on respective ganglia or nicotization to paralyze the latter, does not alter the subsequent action of ephedrine.

(c) *On Secretions*—Ephedrine causes increase in secretion of several organs. In anaesthetized dogs urine and lymph are found to be constantly increased, submaxillary and pancreatic secretion usually augmented while sweat is not affected, by ephedrine. In non-anaesthetized dogs in which a Pavlov or Heidenhain pouch is made the gastric secretion is found to be definitely increased by subcutaneous injection of ephedrine. Free and total hydrochloric acid rises at the same time. Intestinal juice and bile do not start to flow after ephedrine in dogs with Thiry-Vella and bile fistulae respectively, but pancreatic juice is sometimes increased in those with pancreatic fistulae. In all cases except the submaxillary gland when ephedrine exerts influence the results may be probably referable to the changes in circulation.

(d) *Absorption and Toxicity*—Circulatory effects are immediately shown by intravenous injection, less rapidly by intramuscular or subcutaneous injection or by the mouth. Intraperitoneal injection is also effective. The

minimal effective dose in anaesthetized dogs is as small as 0.25 mg. The minimum lethal dose varies in different animals and with different methods of administration. In frogs, when injected into the anterior lymph sac, it lies between 600 and 650 mg per kilo of body weight. By intravenous injection the MLD in white rats is 140 mg per kilo of body weight, in rabbits 70 mg per kilo, in cats 75 mg per kilo, and in dogs 70 mg per kilo. By intramuscular or subcutaneous injection rabbits can tolerate a much larger dose than the MLD and by daily repeated intravenous injections they can stand a dose 840 times the MLD without any pathological changes. There is no doubt that this drug has a low toxicity.

## Ephedrine in Experimental Shock and Haemorrhage

In anaesthetized dogs, ephedrine raises blood pressure in haemorrhage and experimental shock induced by histamine, peptone, anaphylaxis or surgical violence and trauma. The rise in blood pressure is permanent under favourable conditions, and its effect is due to cardiac stimulation and not to arterial constriction. Ephedrine fails to act when the heart becomes impaired or respiration ceases, or the degree of shock is too extensive, or when haemorrhage exceeds 25 per cent of the total volume. It has however, no harmful effects. Clinical use can probably be made in the early stage and in mild forms of shock, or as a prophylactic drug against surgical shock in long operations.

## Clinical Uses

Ephedrine can replace adrenaline in several instances.

(a) *In Hypotension*—The only case of hypotension studied was that of Addison's disease in which intramuscular injections of 100 mg of ephedrine twice daily raised blood pressure from 70/40 mm to 110/68 mm Hg for about two hours and by mouth a single dose of 150 mg maintained the pressure at a high level for over twenty hours.

(b) *In Asthma*—As a broncho-dilator ephedrine appears to be very efficient. In five cases treated the results were most convincing. 20 to 150 mg given intramuscularly never failed to relieve asthmatic attacks completely. The effects come on usually within fifteen minutes at the same time as blood pressure rises. In one case adrenaline was administered before ephedrine but the patient's dyspnoea did not totally disappear until the latter was used. This is considered a temporary relief although none of our treated patients have come back with recurrence of their complaint.

The good features of ephedrine can be most conveniently summarized as follows:

1. Ephedrine is chemically stable, age exposure to light, or boiling does not alter its action.
2. It has a persistent and uniform action in contrast with that of adrenaline.
3. It has a low toxicity. The margin of safety is unquestionably very wide.
4. It can be given very conveniently either per os or by intramuscular injection. There is no local irritation.

## MEDICAL, SURGICAL, OBSTETRICAL

## ESSENTIAL HAEMATURIA

The following details of a case of essential haematuria which occurred in Wuchang, Central China in June 1926 seem to me to be of sufficient interest to merit publication.

A young and otherwise healthy man aged 29 with a negative family history for kidney trouble or any kind had one attack of albuminuria in Egypt in 1917. This was thoroughly investigated radiologically and cystoscopic examination were made without result and no tubercle bacilli were detected. The right kidney only was affected and the albuminuria was thought to be connected with a concurrent attack of appendicitis. The appendix was removed in 1919 and showed sign of previous inflammation. The first attack of haematuria occurred at the end of June 1926. The shade temperature was about 99°F and the patient was working a high pressure mentally and physically but feeling fit. He first noticed blood in his urine after a strenuous game of tennis followed immediately by a cold bath. The urine remained red that day but the following milder—it was much

clearer, and the next day apparently normal. He took his temperature and found it to be normal, and therefore concluded that there was no malaria. He had no pain or general symptoms, and did not have medical advice.

The second attack occurred ten days later, after strenuous physical exertion when the temperature was high. He had been moving boxes up and down stairs, and again had a cold bath in accordance with his habit at that time. The attack was precisely similar to the first and elevated up without treatment.

Shortly after this the patient left the plains and went up some 4000 feet into the hills, where the temperature was about 55° F. He arrived in a state of collapse, due to over exertion and an attack of enteritis on the journey, he slept for thirty six hours after his arrival, and recovered without other treatment than rest and dieting for a few days. There was no haematuria.

The third attack of haematuria occurred after he had been in the hills for three or four days. There was no assignable cause for this attack, which lasted two or three days. He returned to Harrow, where the temperature was unusually high at that time, the haematuria reappeared at once. Microscopical examination of the urine showed the presence of blood cells but nothing further. A radiological examination was negative. Cystoscopic examination revealed a normal bladder and blood stained urine issuing from both ureteric orifices. Ureteric catheterization showed that both kidneys were bleeding. Urine was collected separately from each kidney and examined, and separate injections were made into guinea pigs. Both of these died, one after a few days, and the other after three weeks, but no tubercle bacilli were found at the necropsies. The bleeding was profuse after catheterization, but began to clear up the same day without treatment, it has not recurred up to date. The patient felt quite fit throughout.

This case appears to me to deserve consideration because, in three out of the four attacks, the onset was definitely associated with a sudden change of temperature. In the first two attacks a high temperature was rapidly lowered by cold baths, and in the fourth the patient went from a comparatively cool climate to a very hot and humid one in an hour and a half.

It is obviously impossible to generalize from a few attacks in one patient, but the case is of interest in suggesting a possible type of cause in some cases of unexplained haematuria.

For permission to publish notes on the examinations made in Harrow I am indebted to Dr. Robert And.

### NOSE BLEEDING TREATED BY MORPHINE

I desire to draw attention to the fact that hypodermic injection of morphine quickly controls bleeding from the nose, irrespective of the cause. The following cases illustrate some of the types of nose bleeding in which it has been found of use. In none of them could a local cause of the bleeding be found.

*Case 1*—A married woman, aged 30, six months pregnant, began to suffer from profuse bleeding from the nose at about 9 p.m. She was so extremely nervous that it was impossible to plug even her anterior nares, and all other methods of treatment were of no avail. Twenty minutes after the injection of 1/4 grain of morphine the bleeding had ceased and she had a good night's rest (which would have been unlikely with plugged nares).

*Case 2*—A married woman, aged 60, when recovering from influenza had for several hours slight bleeding from the nose, he bleeding became extremely profuse, and showed no diminution in spite of applying the usual remedies, including adrenaline, but fifteen minutes after injection of 1/4 grain of morphine it had completely stopped.

*Case 3*—A married woman, aged 55, suffering from chronic interstitial nephritis, began to suffer from fairly profuse haemorrhage about 6 p.m. She objected at first to hypodermic injection, but as 1/4 grain of morphine by the mouth had no effect she consented to an injection of haemoplastin (a haemostatic serum) at about 10 p.m. As the bleeding had not stopped by midnight she was given an injection of 1/4 grain of morphine and within half an hour the bleeding had stopped and she spent a good night. It is quite possible that a second injection of haemoplastin would have stopped the bleeding, but it was impossible to obtain more at that hour of the night.

*Case 4*—A man, aged 22, suffering from congenital heart disease, had bleeding from the teeth and nose. There was no history of injury. All the usual remedies had been tried, but without success. The bleeding stopped half an hour after the injection of 1/4 grain of morphine into one arm and haemoplastin into the other. It began again after about twelve hours, and he was given an injection of 1/4 grain of morphine only, the bleeding stopped but recurred next day, it ceased permanently after a further 1/4 grain of morphine given hypodermically.

In all cases the morphine was combined with 1/150 grain of atropine.

### APPARENT INFECTIVITY OF CANCER

General practitioners have often held beliefs which were not confirmed by contemporary research workers, though many such beliefs have since been found to be correct. On the vexed question of the causation of cancer I think most practitioners consider

(a) That cancer is an infection—that is, caused by micro-organisms or organisms.

(b) That there is a predisposing factor, particularly a hereditary predisposition, or a vocational predisposition.

(c) That cancer is communicable, directly or indirectly, from one person to another.

(d) That they therefore regard the spread of cancer from pretty much the same standpoint as that of tuberculosis.

The following is a type of the train of incidents on which these opinions are based.

Mr. X was an indulgent pipe-smoker, renewing an attractive and expensive type of pipe every few weeks. He had business dealings with A, B, and C, all fellmongers, and presented each with one of these used pipes. Unknown to all concerned Mr. X was suffering from cancer of the stomach, and died within a year. Within the next two or three years A, B, and C all died of cancer—A of the tongue and jaw, B of the stomach, and C of the bowel. One of A's family has subsequently died of cancer, another of so-called acute pancreatitis, while two surviving members are suffering from duodenal stenosis, a condition which is common in this area.

I leave the reader to make his own deductions.

Ingleton, via Garaforth

### ACTINOTHERAPY IN JOINT TUBERCULOSIS IN CHILDHOOD

At Alder Hey Hospital actinotherapy has been used in the treatment of tuberculosis of joints in children during the past twenty months. The type of lamps and the technique of treatment used are as follows.

The open framed carbon arc consuming 35 amps at 230 volts, general body baths exposure at a distance of 30 inches for periods commencing at five minutes and increasing to one and a half hours, a similar lamp fitted with tungsten molybdeno-coated carbon electrodes consuming the same current, general body baths at a distance of 33 inches for periods of two minutes increasing to ten minutes. Treatments were usually given three times a week.

In estimating the effects of any treatment in joint tuberculosis in childhood it must be borne in mind that the majority of patients recover under suitable hygiene and dietetic conditions, for example, in a series of 1025 cases of tuberculous hips treated without actinotherapy the case mortality was 7.5 per cent.

All our patients were under 16, they were treated on open-air balconies, and were given cod-liver oil and a diet rich in fats. Spinal and hip cases were immobilized by spinal and abduction frames, and knee cases with Thomas bed knee splints.

Hip cases (20)	Improved	Worse	No change
With actinotherapy	2	5	6
Without actinotherapy	4	3	—
Spinal cases (17)			
With actinotherapy	4	3*	—
Without actinotherapy	6	3	1
* All dead			
Knee cases (8)			
With actinotherapy	2	—	—
Without actinotherapy	5	1	—

Contrasted with other patients suffering from similar diseases, those receiving artificial light treatment on the whole did badly. When sinuses were present the exposure to ultra-violet rays increased the discharge and produced painful inflammatory changes in the surrounding subcutaneous tissue, in a few instances the treatment seemed to increase the tendency to sinus formation by producing subacute cellulitis rather than a typical cold abscess. This was particularly noticed in cases exposed to the tungsten rays. Another objection to actinotherapy is that in practice it necessitates frequent lifting and transport of the patients, who are thus subjected to repeated minor degrees of trauma.

In reviewing the records we find that some of the cases that were not making satisfactory progress under ordinary treatment were treated with actinotherapy, to some extent.

this account for the disappointing results obtained but we are convinced that radiotherapy is of little or no value in the treatment of this form of tuberculosis, in some cases it appeared to be injurious.

We wish to thank Lieut Colonel P. Macdonald the medical superintendent of Alder Hey Hospital for permitting us to publish the case.

Alder Hey Hospital Liverpool

### A PAROXYSM OF AURICULAR FIBRILLATION

In the JOURNAL of May 21st (p. 919) Dr. E. E. Lislett publishes a case of a paroxysm of auricular fibrillation caused by an electric shock. I notice that he expressed the opinion that the condition may have been "flutter" rather than fibrillation. In this connexion I would like to record the following case.

On June 13th 1927, a man aged 49 was admitted to the Waikato Hospital. He stated that ten months previously while mixing rabbit poison he was inhaling some of the powder blew up into his face and was inhaled. He collapsed (fright) and next day an attack of pain in his chest took him to his doctor. The pain passed off in three days. Three weeks later he was again attacked. This time he noticed that he was breathless and that a peculiar fluttering sensation was present in his left chest. Since then he has suffered a sequence of similar attacks at odd intervals which seemed to follow severe physical effort on his part. He stated that his pulse remained unaltered during the attack. He had a thrombosis of the right femoral vein arising from typhoid contracted twenty-five years ago together with a large mass of varicose veins extending across the lower abdomen and an unhealed varicose ulcer of the left leg.

When I saw him he was in bed and had been at rest for some hours. The heart's apex beat was regular (63 to 70) and forceful and was felt about two inches below the nipple. In the nipple line a second impulse could be seen and felt over the auricles. The blood pressure (systolic) was 130 mm Hg. The ventricular systole was 75 regular. The auricular systole was distinctly heard regular and about 200 to the minute no murmurs were heard. The Wassermann reaction was negative.

There being no electro-cardiograph available it struck me that an X-ray might be of value and the patient was removed immediately to the X-ray room where he was screened by Dr. Harris. The hospital radiologist in the presence of myself and Dr. Crawford Dr. Harris reported lateral diameter of heart increased auricles show a rapid pulsation over 200—periodic ventricles show a consistent steady beat 70 to 80.

There was no synchronism between auricular and ventricular systoles.

I demonstrated the case clinically the same night but was told by the patient that we would not see anything as the flint ring had pulled off. In this he was correct. The heart had returned to normal. Auricular and ventricular systoles were synchronous and steady at 85. He was discharged on July 4th and has had no recurrence.

Hamilton New Zealand

### ATRESIA OF VAGINA WITH MENSES RETAINED TO THE AGE OF 26 YEARS

This case is noteworthy in that the condition had persisted so long with trivial symptoms and that the uterus was able eventually to perform all its functions.

At the age of 15 the patient had noticed slight pelvic pain on several occasions at intervals of a month. From that time there had been no discomfort until just before admission to the hospital. There had been no disturbance of the function of the bladder or rectum. She had been aware that the lower part of the abdomen was increasing in size but this she had attributed to fat as she had always been decidedly well nourished. She had married at the age of 21. A few days before admission a black vaginal discharge had made its appearance.

The temperature was 99° F and the pulse 120. On examination of the abdomen a median swelling the size and shape of a six months' pregnancy was found. It was tense and fluctuant and rather tender on palpation. The external genitalia were rather small but otherwise normal. The remains of the hymen were seen and a finger could be passed beyond it for a distance of an inch and a half before being checked by a transverse septum. Further detail could not at the time be made out on account of the black, tarry fluid which obscured everything.

Under an anaesthetic it was found that the fluid was exuding through a pinhole aperture in the transverse vaginal septum. This was incised and the greater part of it was afterward dissected away. From three to four pints of black, grumous fluid flowed out. It had the odour characteristic of a *B. coli* infection and gave a capen along with it. Irrigation with 1% of lot on was continued until the cavity was clean. It was difficult to determine the exact state of affairs the walls of the cavity were flaccid and thin and into irregular oedematous projections the wall was thickened at the summit and very thin in the lower part. It was concluded

that both uterus and vagina had been distended to the three had certainly been no distension of the Fallopian tubes.

A swab taken from the fluid yielded a pure culture of *B. coli*. The portion of septum removed measured 4 cm in thickness. A section showed that it was composed of fibrous tissue with some non-striated muscle and was covered on either side with stratified squamous epithelium.

After the operation there was never any cause for anxiety. The temperature remained about 100° F for three days and then all went well. She menstruated three times in a perfectly normal manner and then became pregnant. She gave birth to a full term living child without any special difficulty.

ALFRED COUGH, M.B., Ch.M., F.R.C.S.,  
Assistant Surgeon Hospital for Women and Children, Leeds.

### INVERSION OF THE UTERUS

Those who have seen a case of complete inversion of the uterus are almost unanimous in emphasising the profound shock attendant upon this accident. In the case reported by Dr. Fotheringham in the JOURNAL of August 27th (p. 350) the time which necessarily elapsed before his arrival, and possibly the manipulations of the midwife, would be ample to account for the condition of the patient. It is comforting to remember that the occurrence of inversion of the third degree is not, at the moment, necessarily accompanied by shock, or haemorrhage, or great pain.

In January 1925 I was called to a young primipara healthy but not at all robust. The liquor amnii had come away twenty-four hours before. The head was well down but the patient was tired out and the pains poor. The head was delivered with forceps under CP anaesthesia and the anaesthetic then withdrawn. After birth of the child the placenta was difficult to expel and rather forcible expression was used but only during uterine contraction. The cord was not pulled upon. At the moment when the placenta appeared to be coming away the uterus was felt to disappear from above the pubes, and the inverted organ still covered by the patient's came out through the vulva. The patient was perfectly conscious complained of no great pain and might have been described as fairly comfortable. After peeling off the placenta the uterus grasped in the right hand was returned into the vagina and manual reduction effected without difficulty.

The surprising absence of shock made me wonder whether the condition usually ascribed to the patient may not sometimes be in reality the condition of the doctor himself—confronted for the first time with a complication which had been a dreaded nightmare to him since his student days.

### SUBCUTANEOUS DRAINAGE OF ASCITIC FLUID

The following details of a case of ascites treated by permanent drainage of the fluid into the subcutaneous tissue seem to be worthy of record.

A woman aged 35 was admitted to hospital suffering from ascites. Her general condition was weak and the liver and spleen were much enlarged but the heart and kidneys were normal. Before admission she had been tapped eight times at intervals of about two weeks and at each tapping nearly 20 pints of fluid was withdrawn.

In similar cases previously I had tried artificial drainage by a short straight cannula and also by passing silk threads through the peritoneal cavity into the subcutaneous tissue of the groin but after two or three weeks the fluid again began to accumulate. For this case therefore I devised a curved silver cannula about 2 inches long with two circular flanges at the curved end. A semi-circular incision was made in the left iliac region and a flap of skin was turned down. The muscles were split by McBurney's method and an opening was made in the peritoneal cavity. One flange of the cannula was inserted in the cavity and a purse-string silk suture was passed through the peritoneum and tied tightly round the neck of the cannula between the two flanges. In order to keep the cannula in position on it was fixed to the muscles by silver wire passed through the holes in the outside flange. The straight end of the cannula pointing downwards was inserted in a pocket made in the subcutaneous tissue. The muscles were tucked and the skin united by metal clip.

At the operation I had left half the quantity of fluid in the peritoneal cavity. This was evidently draining well as on the third day after the operation there was a marked collection of fluid in the subcutaneous tissue of the left iliac region groin and vulva. In order to relieve the excessive pressure of this fluid I tapped the patient completely of lead lotion was applied to the swollen part and the swelling rapidly subsided. The clots were removed on the sixth day and the wound was quite healed. Eighteen days after the performance of the operation the patient was discharged and her husband reported four months later that she was well and that there was no sign of re-accumulation.

## Reviews.

### CONDITIONED REFLEXES

ALTHOUGH Professor Pavlov, together with numerous pupils and associates, has been engaged for some twenty years on the study of the conditioned reflexes, the results of these most valuable researches, which were almost entirely published in the Russian language, have hitherto been almost inaccessible to English readers. By a happy combination of circumstances the results obtained up till quite recently are now placed within their reach. With the assistance of the Royal Society, the translation of Professor Pavlov's book<sup>1</sup> on the subject, which was published in Russian in 1926, has been carried out by Dr G. V. ANREP, who combines the advantages of being a Russian-born subject naturalized in Britain and a former pupil and collaborator of Pavlov's in these investigations on the conditioned reflexes.

On reading through this remarkable book one cannot fail to feel that one is treading on fresh ground, and getting in entirely new aspects of the functions of the cerebral cortex. These functions are treated purely objectively, and even though the treatment may often be, of necessity, provisionally of an empirical nature, the advance is none the less clear. With one step, never to be forgotten in the history of physiology and psychology, this book carries us from the period of introspective observation and impotent speculation into a period of direct experimental inquiry which will extend far into the future.

The method employed in these inquiries is essentially simple in principle, in its applications there is no doubt much advance yet to be made, for almost the only unconditioned reflexes which have been studied up to the present have been those connected with the response to food or other substances placed in the mouths of dogs, the response chosen being the secretion of saliva. If the administration of food is accompanied or immediately preceded by some stimulus to which the animal is normally indifferent, this stimulus comes, after a number of repetitions of this so-called reinforced combination, itself to acquire the power of exciting the alimentary response, even though not reinforced by administration of food. The extent of this response can be measured in drops of saliva secreted in a given time. The stimulus has required the properties of what is called a conditioned stimulus. These facts form the starting-point of the investigations, by an objective method, into the functions of the cerebral cortex in the dog. Anything which can be appreciated by the cortical apparatus can be made the basis of a conditioned reflex. Thus, for instance, the passage of a certain interval of time, as when the conditioned stimulus is habitually given at a certain moment before the reinforcement, may be one of the conditions, these being called trace reflexes, and so on.

Conditioned reflexes are very readily influenced by a variety of inhibitory conditions. For instance, any unusual stimulus will, by arousing an investigatory reflex, produce what is termed external inhibition, so that the normal response remains in abeyance. For this reason the experiments must be conducted in a specially constructed laboratory, in which the animals can be isolated from all undesired stimuli, including the presence of the experimenter. Several chapters are devoted to the subject of inhibition, and it is this portion of the book which gives most food for thought. The descriptions of the spread and concentration of the inhibitory process, of the mutual induction of excitation and inhibition, of the causation of sleep, of the phenomenon of differential inhibition, etc., are all of the greatest interest, but too intricate to be even outlined here.

One or two elementary points can alone be mentioned in order merely to indicate the general nature of the phenomena. The trace reflex has been referred to above as one in which, while the reflex is being built up, a definite time elapses between the conditioned stimulus and the reinforcement. After a certain number of repetitions of

the combination, the passage of this period of time requires conditioned properties, so that when not reinforced the response will only follow after the lapse of this time. What is happening during this period to prevent the stimulus from acting? The answer is provided by the application of some mild stimulus, capable of erasing some degree of external inhibition during this latent period, the astonishing result of such a stimulus is that secretion begins forthwith. The inference is that during the interval the effects of the conditioned stimulus were being subjected to an internal inhibition, and the effect of the external stimulus was to inhibit this inhibition, and so reveal the response which was in abeyance during the interval. That this explanation of the phenomenon as due to disinhibition is the correct one there seems to be little reasonable doubt, for it is supported by much collateral evidence.

If two somewhat similar stimuli are employed, and one of them is associated with reinforcement while the other one is not, then the first becomes a conditioned stimulus and the other does not, by making the negative one nearer and nearer in properties to the positive one it is possible to investigate the powers of discrimination which the animal can exhibit, thus a great deal can be learned of the delicacy of sensation of dogs. In this way it can be shown that dogs can discriminate very small differences of tone, of shape, of direction of movement, of different rates of a metronome etc.

The state of inhibition is physiologically a condition of rest. States of excitation or inhibition have a tendency to spread in the cortex from the site where the process initiates to surrounding zones. This tendency is counteracted by the process of induction, by which an act of inhibition induces a state of excitation in surrounding areas, the processes of irradiation and of induction are thus antagonistic ones. In its functions the cortex acts as a mosaic of kaleidoscopic character, excitation, inhibition, irradiation, and induction playing off in endless variation one against the other. Sooner or later, however, owing to fatigue, the inhibitory process spreads more and more widely, and we have the phenomenon of sleep or, under particular conditions, hypnosis. Often in the performance of these experiments, when certain conditions prevailed the animals fell into a sleep so deep that they were with difficulty aroused. For instance, in trace reflexes with long delay the animals often fell asleep during the interval preceding the response. Many experiments of pathological significance have also been performed: portions of the cortex have been excised, various sense organs damaged, and other similar investigations begun.

It is pointed out that as yet all these results obtained on the dog can only be applied with great caution and much reserve to man. As the subject grows and the fundamental principles of the functions of the cerebral cortex begin to clarify, these applications can be made without doubt, but there is much yet to be done before this stage can profitably be commenced.

The editor, Dr Anrep, is to be congratulated most warmly on the excellence and readability of his translation, as well as on the skill which he has shown in adapting into English an entire new terminology in an undoubtedly difficult subject.

C LOVELL EVANS

### DISEASES OF THE TONGUE

THERE is room at the present time for a new textbook on *The Tongue and its Diseases*,<sup>2</sup> and Mr DUNCAN FITZ WILLIAMS's work on that subject supplies the want in a way which leaves nothing to be desired. It is very complete in regards the various lesions of the organ, mention being made of all the rarer as well as the more common affections, and the subject matter is presented in a manner addressed rather to the practitioner than the student preparing for examination. The recommendations with regard to treatment are put particularly well, cut and

<sup>1</sup> *Conditioned Reflexes*. By I. P. Pavlov. For Mem R S. Translated and edited by G. V. Anrep. MD D Sc. London: Milford Oxford University Press. 1927. (Roy. 8vo pp. xi + 430. 17 figures. 28 net.)

<sup>2</sup> *The Tongue and its Diseases*. By Duncan G. L. Fitzwilliams. M.C. MD. Ch.M. F.R.C.S. Edin. and Eng. Oxford Medical Publications. Oxford: Milford Oxford University Press. 1927. (Demy 8vo, pp. xi + 255, 166 figures, 6 plates. 36s. net.)

dried rules are avoided and the practitioner will find many useful hints and details such as are often missing in more formal textbooks, but which are of the essence of success in actual practice.

The author evidently writes directly from his own personal knowledge while freely inserting descriptions of cases under other surgeons wherever special points need emphasis. In his preface he appeals to medical men to instruct their public as to the curability of cancer when recognized in its early stage, advice which is so repeatedly given in these days that one may suppose that every practitioner must be alive to the importance of it. Cancer is stated to be a curable disease in 80 to 90 per cent of patients in only if it can be removed when it is still local and has not extended into the lymphatic. As regards cancer of the tongue if the operation is done before dissemination has occurred it need not be a huge one in order to establish the diagnosis, and further operation may not be required. This has been emphasized by some surgeons. Trotter for example states "I have never seen such a case in which, after suitable (limited) operation local recurrence has taken place." One of the most important points to remember both for the patient and the medical man, in order to ensure an early diagnosis is that a very characteristic feature of early cancer anywhere is its lack of symptoms—pain, for example. The following statistics are of interest. In Butlin's series of 197 cases 27.8 per cent were well after 3 years, the longest survival being 23 years. Bloodgood, in 260 cases reported that of 36 early cases he had 62 per cent of five-year cures while in 75 cases of late carcinoma he had only 12 per cent of such cures. At the Mayo Clinic, 30.8 per cent were alive after 3 years and 24.4 after 5 years but 61 per cent of these who presented themselves for examination had been rejected as inoperable. Cured in 60 cases had 24 per cent of three-year cures and Cobb and Simmons in 56 cases, reported 14.3 per cent of such cures. The only figures, therefore that give a 30 per cent cure for three years are those of the Mayo Clinic and then only after excluding 61 per cent as inoperable cases. Subsequent operations on the glands although not as promising as primary operations, are still often successful. Treatment of cancer of the tongue by x rays and radium has proved singularly unsatisfactory and it is rare even to obtain any abatement of the symptoms. With regard to the operation for removal of the growth the author remarks that probably

with the exception of a few to whom the compliment may be paid of saying that their interest in the matter is above the average. For surgeons conduct the operation along the following lines. Having decided upon an intracapsular operation they dissect out the submaxillary gland and any carotid glands they may find lie to the lingual artery and then proceed to the removal of the tongue. If the whole tongue is to be removed both sides of the neck will need to be dealt with in the above manner. It is not too much to say that the after results in these cases are as bad as any we have in surgery.

The author considers that, in the first place it is not necessary to ligate the lingual artery, and secondly that it is quite inadvisable to remove the tongue locally and dissect the neck at the same operation, the latter should be done as a distinct operation a fortnight after the local removal of the tongue when the mouth wound has healed. The best mode of administering the anaesthetic he considers to be through a small transverse incision in the crico-thyroid membrane, and he holds that laryngotomy is preferable to intratracheal anaesthesia, not only in cases of large fungating growths, but also in those of small size.

As to the best anaesthetic to use he remarks

We know that the number of deaths upon the table is greater with chloroform than with ether. I am certain however that if the deaths were taken for fourteen days from the commencement of the operation the figures would be reversed and the ether deaths would exceed those of chloroform in a most decided manner.

He remarks on the importance of having the ether warmed, and on the tendency of a preliminary injection of morphine to prevent the rapid return of the coughing and swallowing reflexes which are of such importance in operations of this character.

## THE PSYCHOLOGY OF THE EMOTIONS

*Emotion and Insanity* is the title of a translation of a monograph by Dr S. THALBITZER, chief of the medical staff in the Copenhagen Asylum. This work is essentially a contribution to academic or "pure" psychology rather than to psychiatry. A descriptive study of the variations in mood in the manic depressive psychosis is utilized by its author to throw light upon the nature of normal feeling and emotions. Dr Thalbitzer points out that we have learnt much about the centres now definitely established in the cerebral cortex, and of their tracts to and from the periphery, from the investigation of cases of degeneration of those tracts brought about by disease. Similarly, he commands no profit by the study of mental diseases in order to arrive at an understanding of the corresponding normal conditions.

The author's argument, and clinical investigation lead him to a conclusion which strongly favours the existence of a "feeling centre." He considers it to be definitely established that feeling is not a by-product of brain cells which have another function and argues that if we recognize feeling to be an elementary psychic function we must also acknowledge that it proceeds from its own cells which are collected in a "feeling centre." Furthermore from the physiological point of view this centre must, he thinks, behave in exactly the same way as all other bodily organisms especially in that its specific function can only increase or decrease the change make itself known psychically as excited feeling (pleasure) or depressed feeling (displeasure). He agrees that as to the position of this feeling centre we have no certain knowledge, but he brings forward arguments in favour of the view that it is probably situated in the occipital lobes (gyri occipitales).

The book raises problems of interest both to the neurologist and psychologist. It is eminently readable and its argument well suited. Professor Hoffding writes an appreciative preface.

## DISEASES OF THE NERVOUS SYSTEM

A new impression of the late Professor DEJEAN's well known *Sémiologie des Affections du Système Nerveux* has made its appearance. The first edition was published in 1900 and the present volume is a reprint of the second edition, published in 1914. No alteration has been made in the work as written by Professor Dejean, but the index has been made more complete. This book is not written on the usual plan of the average medical textbook, which deals successively with the etiology, symptomatology, diagnosis, and treatment of individual diseases. It assumes that the reader has sufficient knowledge of the essential facts of anatomy and pathology as they apply to the nervous system and proceeds at once to consideration of the syndromes of disease in the widest sense to include the subjective and objective symptoms, their differential diagnosis, their pathology and their mode of production. The great clinical and pathological experience of the author enabled him to carry out this plan to perfection.

The volume contains over twelve hundred pages of text with 564 figures and 3 plates, it is well produced and well bound. Detailed description of a classical work of this magnitude is not possible and is not called for. The main divisions of the chapters are into disorders of the higher mental faculties (coma, affections of sleep, apraxia, and so on), disorders of language or movement of sensibility or co-ordination of the reflexes of the vegetative nervous system, and of the special senses. One chapter moreover, is devoted to the significance of changes in the cerebrospinal fluid. In the particular copy before us an error of binding has led to the repetition of certain pages (pp 1073-1088) and the omission of others (pp 1089-1104).

\* *Emotion and Insanity*, by S. Thalbitzer. With a preface by Professor Harald Hoffding. Translated by M. G. Beard M.A. Oxford: The International Library of Psychology, Philosophy and Scientific Method. London: Hegan Paul, Trench, Trubner and Co. Ltd. New York: Harcourt, Brace and Co. Inc. 1926. (Demy 8vo pp. vi + 325, 76d. net.)

\* *Sémiologie des Affections du Système Nerveux*, by J. Dejean. Reprint of the 2nd edition. Paris: Masson et Cie. 1914. (6 1/2 x 10 1/2, pp. xxvi + 1220. Six figures on plates 1, 2, 3, 4, 5, 6.)

Dr PAUL VAN GEHUCHTEN has edited and revised a new edition of *Les-Maladies Nerveuses* of the late Professor A VAN GEHUCHTEN of Louvain. The first edition, prepared originally in 1914, but published shortly after the war, was exhausted over a year ago. The present edition maintains the same general character as the first, but much revision and addition has been necessary to bring it into line with the important extension of knowledge which has taken place since 1914. Diseases such as the Parkinsonian syndrome, the chorea of Sydenham, and the epilepsies can no longer be classified as functional disorders, though their exact organic basis is still not clearly defined. Lesions of the corpus striatum and the extrapyramidal system have been brought into prominence by the devastating effects of epidemic encephalitis. Due attention is given in the new edition to these fresh factors in neurology, as also to new diagnostic methods such as the introduction by Sierd in lipiodol in the localization of the site of spinal compression, and of ventriculography as an aid to the diagnosis of cerebral lesions. The description in the first edition of the spino-thalamic tracts as traversing the cerebellum is abandoned in favour of the modern view. The general plan of the book follows the systematic teaching given at the University of Louvain, and a very comprehensive account of nervous diseases is provided on lines essentially clinical. The printing and paper are excellent, and it is unfortunate that so important a book should be issued with a paper binding which soon parts company with the leaves and makes the handling of the book, necessarily a heavy one, awkward and irritating. The illustrations are altogether admirable, the large majority being photographic reproductions of cases or of microscopic sections.

The clinical lectures in neurology and psychiatry delivered to students of the Ecole du Val-de-Grâce (Ecole du Service de Santo Militaire) have been put together in a volume by Dr A. ROUQUIER, Professeur Agrégé in the school. It is of moderate size and is designed as a summary of modern views on neurology and psychiatry for the benefit particularly of general practitioners and junior hospital workers. It is written essentially from the clinical point of view as an aid to the investigation of cases, but considerable space is devoted to anatomical and physiological considerations which are necessary for an understanding of the abnormalities of function manifested by disease. Thus reference is made to modern work on the extrapyramidal motor system, on cerebellar function, and on the reflex functions of the spinal cord. In a book with the objects mentioned a certain dogmatism is permissible, but on the whole the author has been careful to distinguish hypotheses from facts, especially in his descriptions of recent views on the subthalamic region. One might have expected more reference to the work of Heid and Riddoch on the functions of the isolated spinal cord in man, owing to its important practical bearing. The clinical accounts of nervous diseases are succinct and clear, and the general plan of the book is excellent.

### THE PLAGUE

THE last severe epidemic of plague in London, which was followed by the Great Fire, has impressed itself so deeply on our imaginations as "The Great Plague" that we are apt to forget that it was only one of a number of terrible epidemics, just as the fire was not the only great conflagration in the city, although it was the greatest. The genius of Defoe has given us a fictitious account which has so much truth in it, and, like all his work, has such an air of fact, that the mind's eye is apt to be focused only on the nearest of the series of epidemics which ravaged Europe during at least three centuries. Readers of Dr Crichton's *History of Epidemics in Britain*, and of Mr Walter G Bell's more recent work on the Great Plague in London

in 1665, know better. Mr F P Wilson's book on *The Plague in Shakespeare's London* now comes as a useful reminder of the facts, as far as the first half of the seventeenth century is concerned, for Mr Wilson does not tie himself down to the period covered by Shakespeare's life, but includes the great epidemic of 1625, which occurred nine years after his death. In this year it is computed that more than one-sixth of the population of London died of the plague, and the impression made on contemporary writers was thus expressed by the author of *Lachrymæ Londinenses*: "to this present Plague of Pestilence, all former Plagues were but petty ones." This to future Ages and Historiographers must needs be remembered the Great Plague." The writer could not know that forty years later the pestilence was to take over one hundred thousand lives in an epidemic that would be known to posterity as the "Great" plague, and he was probably unwary of the terrible visitations which occurred before his time.

Both Mr Walter G Bell and Mr Wilson impress upon us the fact that plague was always a scourge of the poor and lowly. Hardly any persons of note died of it in all the epidemics, either because they found safety in flight or because then better circumstances protected them from the rat-flea. Yet no one in England then suspected the rat of being the harbinger of infection. Dogs and cats were condemned to death, and great numbers of the first-named were slaughtered, so great that we are led to think that London must have supported a dog population comparable with that of Constantinople in more recent days, before the Young Turks ruthlessly deported their quondam servants. Mr Wilson says that the statement of Defoe that 40,000 dogs were killed during the plague of 1665 does not sound to him extravagant. There are many interesting illustrations to this book, among which that of the rat catcher on page 37 is most attractive. This artist appears, like the Pied Piper, to be dancing, and performing a complicated cross-legged step which is hardly consistent with rapid progress, or else he suffers from ankylosis of both hips in an adducted position, which would surely hinder his success as a captor of so nimble a rodent as the rat, whether black or brown.

In his preface Mr Wilson tells us that he began this work as a commentary on some pamphlets of Thomas Dekker, the dramatist, on the plagues of 1603 and 1625, but he has gone far beyond his original intention and made very extensive researches which have resulted in the production of this learned and well documented work.

In an appendix he gives a valuable account of the origin and history of the bills of mortality, with photographic reproductions of some of the rarest of them. It will be remembered that we called attention to this interesting subject in an article under the head "Nova et Vetera," published a year ago (October 9th, p 645). Mr Wilson's chapter on the population of London in the early seventeenth century contains much that is of value, although in the absence of anything like a census all estimates before 1801 must remain more or less conjectural.

What of the members of the medical profession in the plague years? We fear they showed little more courage than the clergy, though it could be said for the physicians that most of them went with or followed their patients into the country, probably their absence or presence had little or no effect on plague mortality, for, knowing nothing of the cause or the pathology of the disease, they were quite unable to treat it successfully. Yet by unconscious suggestion the physician was no doubt able to hearten and soothe and give hope to him and his relatives. There were notable exceptions among the physicians to the rule of flight. Some of the best, such as the great Francis Glisson, stayed in the infected city and saw the epidemic through. There was, however, some provision for the medical care of the plague-stricken, for in 1625 the city spent £290 6s 8d in fees for this work, and the name of the surgeons to the pest house in 1606 and 1625 are on record.

*Les-Maladies Nerveuses*. By Professor A. van Gehuchten. New edition revised by Dr F. van Gehuchten. Louvain: Librairie Universitaire, 1926. (Roy. 8vo, pp 694, 412 figures.)  
*Travaux de Neuro-psychiatrie à l'Usage des Étudiants et des Praticiens*. By Dr A. Rouquier. Paris: Gaston Doin et Cie, 1927. (Mod. 8vo, pp 270, 9 figures.) 32 fr.

*The Plague in Shakespeare's London*. By F. P. Wilson. Oxford: The Clarendon Press, 1927. (52 x 9, pp xi + 228, 25 illustrations.) 12s 6d net.

Mr Wilson's work professes to deal with plague in London only, but other towns and even country places suffered as severely, although, being small, the mortality does not impress the imagination as do the vast totals of the metropolis. As a matter of fact and as Mr Bell has pointed out, the last epidemics of plague in England occurred after the great one of 1665 not in London but in provincial towns, among which Nottingham had the misfortune to be the last instance if, as is probable, that epidemic was really one of plague.

### X RAYS IN DERMATOLOGY

The administration of x rays in appropriate dosage forms such an important part of dermatological therapeutics that we welcome Dr O'MALLEY'S translation of the work<sup>1</sup> on this subject by Drs ARZT and FENS of Vienna. Their practice differs somewhat from that in fashion among British dermatologists, and their advice on the choice of apparatus might well have been modified by the translator to meet British requirements for the original authors have naturally considered only apparatus of Teutonic origin. Nevertheless the principles to be followed by the purchaser of an x-ray outfit intended only for dermatological therapeutics remain the same, and, *mutatis mutandis* to suit local conditions, the advice holds good. In fact, the authors evidently conduct their procedure with great care and scientific precision—precautions eminently necessary in the use of x rays, which are agents of such potency for evil as well as good—and those who follow their advice should get good results in practice without risking their own health. As the authors say, there is nowadays no excuse for the occurrence of x-ray dermatitis in those who employ x rays for medical purposes.

Like other workers, the authors recommend in almost all cases the employment of filtered rays, which they consider much safer than unfiltered. The most striking difference between their methods and those in vogue here is in the epilation of the scalp. They have modified the original Kienbock-Adamson method by dividing the scalp into six areas instead of five, and they take three days over the whole operation, as they do only two areas each day. This spreading out of the work is for the purpose of avoiding x-ray sickness and meningeal irritation. These, however, are dangers which, in our opinion, hardly exist. At all events, we are aware of long series of cases of ringworm treated in this country in which the whole scalp has been epilated at one sitting without any ill effects of any kind. Moreover, in Vienna after epilation has taken place the scalp is twice desquamated by the application of iodine. Possibly the large-spored ringworm common in Austria is more resistant than our microsporon, and requires this extra attention.

The translation is good and clear for the most part, but in a few places the meaning is ambiguous owing to clumsy phraseology. All dermatologists and radiologists will find the volume useful.

### NOTES ON BOOKS

It has been said by many people of Mellor's *Chemistry*<sup>1</sup> that wherever they glance at a page they want to go on reading. Such a compliment deserves to be recorded for it cannot often be said of an encyclopaedic work of reference. We have referred previously to the first six volumes at the time of publication and have mentioned the abundance of detail incorporated, the connected order of arrangement, the clear manner of expression and the facility with which everything sought can be found. The seventh volume is now before us and we observe that the qualities shown in the preceding six are undiminished. The seventh volume deals with titanium, zirconium, hafnium, thorium, germanium, tin, lead and the inert gases, as they are here called, following the physicist's nomenclature. It would seem more proper however, that these gases, which include helium, neon, argon and others, should be called the inert elements. The rarer elements

of the above named group offer numerous features of special interest to the chemist and thorium, which has a considerable economic importance, presents many difficulties to the technologist. To many this volume will therefore, be especially valuable for the ready access it affords to all available information concerning them. The chapters on the commoner metals, tin and lead are characterized by the variety of interests presented in different fields of study. Among these the crystallographer and the metallurgist will find a mine of information. The whole, when completed will be a monumental work of a standard of excellence worthy of the science which it serves.

Dr J. SIM WALLACE'S little work on *The Teeth and Health*,<sup>2</sup> which is one of the latest additions to the series of Modern Health Books edited by Professor D. Fraser Harris, contains a popular exposition of the anatomy of the teeth, the physiology of mastication, cause and prevention of pyorrhoea, and focal sepsis and infection. In the concluding chapter the importance of a diffusion of knowledge of the principles of oral hygiene is emphasized. The work is especially suitable for school teachers and those engaged in the education of children.

That only after nearly twenty years has the small volume *Aids to Tropical Medicine*<sup>3</sup> reached its third edition perhaps speaks for itself. In the preface to the first edition the author stated that it does not in any way aim at providing a 'text book' on the subject, but is rather intended to form a student's notebook. Frankly, however, it would not seem to serve any useful purpose to the present day student of diseases of warm countries.

The seventh edition of CURRIE and PUGH'S *Practical Nursing*<sup>4</sup> which has appeared a little more than three years after the last (see JOURNAL, September 20th 1924, p. 524) has been enlarged and revised by Dr Gordon Pugh who has added 100 pages and 50 illustrations. The principal additions will be found in the sections concerned with milk and dietetics, ward work and hospital administration, diabetes and insulin treatment, infant feeding and diseases of childhood, the nursing after special operations and of orthopaedic cases, and the use of ultra violet light and x rays in diagnosis and treatment. Another new feature is that all the questions which have been set at the various examinations of the General Nursing Council of England and Wales for the certificates of general nursing, sick children's nurses and fever nursing from the beginning to the present time have been included in an appendix.

It appears that at the Harvard Medical School it is the custom of the professor of medicine, Dr F. V. PEABODY, to address the students on 'The care of the patient.' One of the professor's little talks has been reproduced under this title in book form<sup>5</sup> from the columns of the *Journal of the American Medical Association*. Dr Peabody's text is that while the treatment of a disease may be entirely impersonal, the care of a patient must be completely personal and he asks whether it is possible for the student to form such personal relationship in an impersonal institution such as a hospital. He finds that it is possible and urges the student to approach the patient with sympathy, tact and consideration to get his confidence so that the patient may come to regard the student as his own personal physician and all the rest as mere consultants. Sickness says Dr Peabody produces an abnormally sensitive emotional state in almost everyone in major cases the emotional state repercussions on the organic disease. Even so-called functional diseases are just as real to the patient as organic disease, and the student's interest in the patient should not evaporate when organic disease has been excluded. Rather should he be stimulated to search further for the cause that has remained hidden and so prepare himself for the more personal relationships which are inherent in the private practice of medicine. The book should be not only useful to the student but also a pleasing reminder to the practitioner of one of his chief functions in curing the sick.

Dr STEPHEN KAY of Mackay, Queensland appears to dislike Jews to despise Englishmen and to loathe Spaniards. In a collection of *Travel Notes*,<sup>6</sup> originally written for the Mackay

<sup>1</sup> *The Teeth and Health*. By J. Sim Wallace, D.Sc., M.D., L.D.S. The Modern Health Books. London: Faber and Gwyer (The Science Press), 135 (Fcap 8vo, pp. 21, 8 figures, 2s. 6d. net).

<sup>2</sup> *Aids to Tropical Medicine*. By Gilbert P. B. Currie, M.A., Cantab., L.R.C.P. Ed. D.P.H. Third edition revised. London: Baillière Tindall and Cox, 1927 (Fcap 8vo, pp. x + 223, 5 figures, 1 plate, 4s. 6d. net).

<sup>3</sup> *Practical Nursing including Hygiene and Dietetics*. By the L. E. Herbert, E. Cuff, M.D., F.R.C.S., and W. T. Gordon Pugh, M.D., B.S. Seventh edition, rewritten and enlarged. ## HOSPITAL POLICY A CHALLENGE

DURING the past eight or nine years there have been many discussions on hospital policy. At the time of the formulation of the hospital policy of the British Medical Association discussion was acute. So sharply is opinion divided upon some points at issue that give fears were expressed that the pressing forward of the policy formulated by the Council of the Association, and submitted to the Divisions and Representative Body, would result in a cleavage amongst members. But the policy was accepted the fears have not been realized, the policy has stood the test of severe criticism, some of it has come into being, some of it is still an ideal to be attempted. The essential features of that policy may be summed up thus. A wider outlook for statutory hospitals, the preservation of the voluntary hospitals and their expansion for other than charitable patients, the co-ordination of all types of hospitals by advisory committees so that there shall be interaction and not competition. Short in brief, is the basis of the policy of the Association. It has received very wide acceptance and not least by the medical profession at large. It was however challenged by the Labour party in a pamphlet which urged what may be summed up in the word nationalization, yet in a conference subsequently promoted by that party, in which many other sections of the community were represented, together with our Association there was a considerable modification of this academic pronouncement, even by the Labour representatives.

A new challenge has now been made by a member of our profession, Mr E. W. Hey Groves, professor of surgery in the University of Bristol, in his presidential address to the Bath and Bristol Branch of the British Medical Association. To refresh our readers' memory, three or four salient passages may here be quoted. It is the fashion now for all speakers and writers on our present hospital system to begin by assuming that there is something sacrosanct about the voluntary hospital system and that it is our first duty to save this at all costs. Now I would begin by challenging the truth of this assumption. I should like to say boldly 'that the voluntary hospital system is dead. The system is not dead but moribund and its protracted life is kept going by stimulants and artificial respiration. The reasons given for this opinion are various. The hospital which began as a mere hostel for the sick poor has now to be a laboratory for scientific work, for prevention, diagnosis, cure, and discovery. The problem has become too vast for the voluntary hospitals. Many of our voluntary hospitals are out of date old buildings badly placed in unsuitable sites [they] have not kept pace with the growth of the population or the increasing demand for hospital treatment made by a larger proportion of the citizens. The lists of patients waiting for admission are becoming longer and the municipal and Poor Law authorities are forced to build hospitals to meet the need. Our present hospital system is radically wrong. It is wrong

because it consists of isolated units without public control. No one hospital unit is perfect or self-contained, and there exists no co-ordination between the units by which the deficiencies of one may be made good by provision in another. No financial assistance of the voluntary hospitals can make good this radical defect unless such assistance is accompanied by a condition for unification under a central control. These extracts from the paper fairly represent we believe, the gist of the challenge. A brisk correspondence followed in our columns mainly from West Country men, since Bristol was the vortex of the storm. But the matter is of more than local interest—since it may be supposed that Bristol methods do not differ essentially from those of other parts of the country.

It seems clear from the trend of Mr Hey Groves's paper that he is dissatisfied primarily because certain hospital facilities that he deems essential are not forthcoming. For this he lays the blame on the voluntary hospital system. He holds that if there were a complete and efficient State hospital system under central control all the things he regards as necessary would soon be obtainable. That there are many flaws in our hospital system or lack of system may be admitted freely. But it does not necessarily follow that another system would be better for us. Mr Hey Groves assumes that the ideal he has so clearly in mind would be attainable under a State system. This is a big assumption and we doubt the validity of it. For a couple of generations statutory authorities in this country have possessed wide powers for the provision of hospitals and already the beds in such institutions far outnumber those in the voluntary hospitals. Enormous sums are spent on them out of the rates and the unadvertised work done by them is a great boon to the communities they serve. But although the standard of professional service in these institutions is steadily improving and many of them now do first-rate work in an atmosphere of kindness and sympathy, they labour under disadvantages some of which seem inherent in any system of State or municipal control. To bring the voluntary hospital under the sway of statutory authority might not improve the voluntary hospital; it might indeed, destroy it. Further, the local statutory authorities have power to provide all that Mr Hey Groves demands and it seems rather hard to blame the voluntary hospital system for the failure.

Mr Hey Groves takes the schools as his chief home illustration of the advantage of State control. It is true that the State has an almost complete monopoly of elementary and secondary school education. Educationalists however are by no means satisfied with it; they do not get all they want. But education as a whole is not a State monopoly. The public schools and universities though many of them now receive grants from public money are not subject to State control. The foundation and corner stone of education is independent and therein as most of us believe, lies the saving grace of our educational system. We discovered during the war how harmful could be the effect of the control of a centralized State over its universities. Public opinion became machine-made. The great voluntary hospitals are in a very real sense the universities of medicine in this land and as such are better free from bureaucratic interference. This, however is far from saying that more co-ordination and more co-operation between voluntary and municipal hospitals are not to be desired. As will be gathered from Mr Herbert Mason's candid discussion on

of that question when opening the debate in the Section of Medical Sociology at Edinburgh (printed at page 575), his ideal for the London area (assuming continuance of the voluntary system) is some kind of joint management, with the voluntary hospital taking a predominant share and the municipal authorities having representation upon the governing body of the voluntary hospital. So long as the voluntary hospitals remain efficient and economical they will, he believes, survive, otherwise "the State or the municipality will swallow up the last remnant of a system that is peculiarly adapted to the British genius, and that has been the foundation of British medicine and British nursing."

It is well to bear in mind, when contrasting the state-controlled with the voluntary institution, that the Continental hospitals which have so impressed some visitors from these islands are in countries where centralization is the rule of the State. With us the reverse is the rule, local initiative is cultivated to the utmost, and the central authority is mainly advisory and auxiliary. There are two distinct principles of government, springing from different habits of mind, and the growth of centuries of custom and tradition. Both have then merits, both their defects. But readers of Bryce's classical work on *Democracy* will be left with little if any doubt that English speaking peoples have a genius for local initiative and local government, and especially for local voluntary societies, and that to this peculiar gift is due the stability of our institutions. The Prince of Wales, who has a talent for putting the common sense view of a thing in a phrase, said last year "Great Britain is a country in which voluntary causes have always flourished, and it is very desirable to foster the spirit of public service on which they are based, because that spirit is one of our best assets as a nation." Central control sometimes looks as though it could achieve wonders, but it is open to question whether life in such circumstances is always so perfect as it may appear from a distance. By one of those happy chances that are provided by the Annual Meeting of the British Medical Association, the visitors to Edinburgh last July included a distinguished surgeon from the capital city of a great Continental State where hospitals are under central control. He was much interested in our methods of electing the staffs of voluntary hospitals, and he then told of the extraordinary and seemingly inevitable things that happened under central control—things he deplored but for which he saw no cure. If this experience is at all general, then "an authoritative body, which should regulate hospital staffs" might not prove an unmixed blessing.

Many other matters of great interest were raised in the course of this address to the Bath and Bristol Branch. Several have been discussed in our correspondence columns, notably by Mr C. E. S. Flemming and Mr Charles A. Morton. In regard to the main point at issue, we may end by recalling a significant remark made by Mr Hey Groves when describing the origins of the voluntary hospitals in Bristol. "The Royal Infirmary here," he said, "was started by Churchmen and Tories, the General Hospital by Nonconformists and Radicals." Is it possible that this may have been the fruit of an attempt some centuries earlier on the part of the State to act as "an authoritative body" in one great branch of the affairs of its citizens? The State forced a central control and made a cleavage that seems irreparable. An attempt to impose rigid

uniformity in hospital affairs might do the same, and destroy for ever the beneficent association that is slowly growing up between statutory and voluntary hospitals.

## LIVER EXTRACTS IN ANAEMIA

PERNICIOUS anaemia has long been regarded as an outstanding example of those diseases in which every new method of treatment has raised great hopes—hopes which have flourished for short periods and then withered in every instance. It is therefore particularly gratifying that the treatment of this disease by liver diet which was introduced by Minot and Murphy appears to be an undoubted advance, for the optimistic claims first made have been confirmed, not only by the discoverers, but also by numerous other investigators. Minot contributed a paper on the subject to the discussion on the pathology and treatment of pernicious anaemia in the Section of Medicine at the Annual Meeting in Edinburgh. A short note on it was embodied in our brief report of the discussion published on August 8th (p. 211), and the full text will be printed in an early issue.

The history of this discovery is of interest, for it furnishes an excellent example of the way in which the results of laboratory research can be made the basis of a great advance in therapeutics. For many years Whipple and his co-workers experimented on the treatment of secondary anaemias in dogs. Their results were very remarkable, for they first showed that treatment with iron salts produced little or no benefit in such cases, and then found that diets of meat and liver produced rapid regeneration of the blood corpuscles and haemoglobin.<sup>1</sup> This work led Minot and Murphy<sup>2</sup> to try the effect of a diet containing an abundance of liver and muscle meat on blood regeneration in pernicious anaemia. The diet they used contained from 120 to 240 grams of cooked liver. This diet produced a very remarkable improvement in forty-five patients with pernicious anaemia. At the same time Koessler, Maurer, and Loughlin<sup>3</sup> reported experiments on rats which led them to conclude that a supply of vitamin A was essential for blood formation. Minot and Murphy<sup>4</sup> have this year made a further report on the results of treatment of 105 cases of pernicious anaemia. Their diet includes, besides about 200 grams of cooked liver, also plenty of fruit and at least 70 grams of red meat. Out of 105 patients, 99 reached a level of 4 million or more red blood corpuscles per cubic millimetre, and in all cases there was a general symptomatic improvement corresponding to the rise in red blood corpuscles. As far as is known the improvement can be maintained permanently, for already twelve cases have shown improved condition for two years or more. Koessler and Maurer<sup>5</sup> have made similar observations on forty-two cases treated with liver diet. These workers now agree that the improvement cannot be attributed to vitamin A alone, and admit that there is a factor in the liver which has a specific action on blood regeneration. The therapeutic value of the liver diet has been confirmed by other clinicians in America, in this country, and in France.<sup>6</sup> There is, therefore, no reasonable doubt that a very important therapeutic advance has been made, and also that our current

<sup>1</sup> Whipple, Robscheit, Robbins, and Hooper, *Amer. Journ. Physiol.*, 53, 36, 1920.

<sup>2</sup> *Journ. Amer. Med. Assoc.*, 87, 470, 1926.

<sup>3</sup> *Ibid.*, 87, 476, 1926.

<sup>4</sup> *Ibid.*, 89, 759, 1927.

<sup>5</sup> *Ibid.*, 89, 768, 1927.

<sup>6</sup> *Ibid.*, 89, 535, 1927.

beliefs regarding the factors controlling the formation of red blood corpuscles and haemoglobin will need considerable revision.

It is obviously of great importance to know the nature of the active substance in liver. This knowledge is of theoretical interest and also of considerable practical importance, because the daily consumption of half a pound of liver is no easy task for a patient suffering from pernicious anaemia and some more concentrated supply of the active principle is obviously desirable. Cobin Minot and co-workers have carried out a series of chemical investigations on this subject. Fortunately, the feeding of the active substance to a patient suffering from pernicious anaemia causes an increase in the number of reticulated red blood corpuscles within nine days, and thus it has been possible to recognize the presence of the active fraction within a reasonably short time. The liver proteins have been found to be inactive and it has been ascertained that the active fraction is insoluble in ether, acetone and cold alcohol. The active substance is free from lecithin and ordinary lipoids, it contains only traces of protein of sulphur and iron. This active fraction of liver tissue produces effects when 10 to 20 grams are given to a patient daily and therefore a considerable concentration of the active principle already has been achieved. The facts mentioned show that the active principle is not a protein or a lipid, and that probably it is not an iron compound. The paper to which we have just referred was written in April and in a private note dated August 30th Dr Minot informs us that down to that date twenty-five cases had been treated (each for over two weeks) and that all had been greatly benefited. It has been ascertained that the material is now free of iron, protein and carbohydrate and appears to be either a polypeptide or a nitrogenous base. There is evidence that the richer it is in nitrogen the more powerful is its effect and that the result is not due to any known vitamins.

Obviously the isolation of a fraction that can only be identified by its curative action on a relatively infrequent disease presents a biochemical problem of somewhat exceptional severity. Doubtless however before long biochemistry will add this to the numerous triumphs it has already achieved.

## THE PHILOSOPHY OF QUACKERY

PROFESSOR A. J. CLARK'S breezy paper on the historical aspect of quackery read to the Section of the History of Medicine at Edinburgh and published in this issue, argues that the growth of science and its increasing application to medicine have done little to influence public discrimination between orthodox practice and quackery. If this were true it would be a disquieting thought for the settled judgement of the public as a whole is rarely in error on a question of imposture. There seems however to be room for doubt whether Professor Clark has not overestimated the significance of some of the signs he has enumerated. The truth seems to be that those who are led to accept or appeal to quack treatment do not represent the opinion of the mass of their fellows nor does their action express their own permanent convictions. They are for the most part only temporary wanderers from the true path. Various and complex are the motives which determine the choice between the legitimate practitioner and the quack, one significant fact deserves attention. Nobody ever goes to a quack for diagnosis

At the sudden onset of severe illness the first appeal is almost invariably to the quibbled medical man. The fact is pertinent, for a diagnosis is always the sufferer's first desire; he wants to know what is the matter with him. If ever it appears that no diagnosis but only relief is wanted, it is either because a diagnosis has been assumed or because the impression has been formed that the diagnosis is obscure or uncertain. There are a few exceptions, for it is inevitable that the prejudices of mankind should take very diversified forms and a few individuals will adopt fantastic expedients even in acute illness, how very few these are may be adduced from the negative evidence of the coroners' courts.

But, notwithstanding all that science has done for medicine there are still cases which are obstinate and do not yield to treatment. Numerous also are the cases in which a remarkable recovery has been made after a period of failure to mend. Whoever has made a recovery in such circumstances will believe and continue steadfast in the belief that what cured him was the stuff he was taking when he got better. His gratification will lead him to extol that remedy above all others and if it happens to be a private or domestic formula his confidence in its efficacy may induce him to exploit the sale of it. Some quack remedies arise in this way not all indeed for some are founded on conscious fraud. It is a remarkable fact that for every quick medicine no matter how worthless there are always to be found a not inconsiderable number of people who honestly believe that it has cured them after the continued failure of other forms of treatment. A great many quick remedies originate from an episode of that kind. The simple fraud of obtaining money by pretence that is purely false as in selling pills of bicard crumb or pills of sugar appears now almost or entirely to have ceased. Only rarely is the cunning of the pure charlatan seen as in selling pills of some synthetic dye with pamphlet literature declaring that the colour of the urine would show the humours of which the body had been purged.

The inborn faith in the virtue of drugs with which great numbers of the people are imbued may be the heritage of a primitive instinct by which man sought to better his bodily estate with something foreign to his ordinary diet. It is invariably accompanied by the desire to prescribe for others. This faith not only fosters quackery but is the source of a perpetual and absorbing entertainment to patients with imaginary or very minor ills. Such are always to be found among the outpatients of hospitals and dispensaries. It is tellingly related of two old ladies, outpatients of a London hospital, that having tasted each other's medicine and having decided that the other was more suited to her own complaint they at once agreed to swap. In contrast to these people it is curious to find a certain number who regard everything medicinal as noxious or venomous stuff. The reaction arises from a sentiment no less human and natural than the liking for medicine felt by others. Closely related is the opposition to vaccination and it is not wholly surprising to find it among educated people. And when the educated man feels that medical science should protect him from small pox by a less obvious method than poisoning his blood with a virus he is only paying medical science a compliment dictated by his acquired confidence in its powers. It cannot be doubted however that most objections to vaccination arise in the face of danger of infection from small pox and a method of combating the spread of the disease has actually been founded on it. Although faith, hope, and prejudice

continue to offer scope for the activities of the dealer in quack remedies, yet the esteem in which rational medical methods are held is higher than it has ever been. Less than fifty years ago there were many people who obstinately refused to go to a hospital for treatment even when there was no hope in treatment at home. There is now no class of people so ignorant, but in serious illness it is their first desire to be admitted to a hospital. The interest with which medical science is followed by the public is noteworthy. Questions are asked by a patient's friends such as "Has he not been x-rayed?" or "Has his blood been examined?" When people take that amount of interest in the doctor's work it is no matter for astonishment that they are quick to recognize a lack of efficacy of treatment, and it is only human nature for the patient who is making no progress to try a little gamble in quackery. After all, he argues, did not a gipsy woman cure his warts when he was a boy with juice ofcelandine after the doctor had failed with all his caustics?

### THE COST OF INTERNATIONALISM

LINGUARY discussions (a correspondent in Geneva writes) have taken place this year in the Assembly of the League of Nations on the financial position of the League. Discussions on this subject take place every year, but this time the hand of the economist seems to have been more evident. It was only after discussion and hesitation that the Commission entrusted with financial matters granted the small credit for the assistance of health activities in Latin America. The proposed setting up of a central opium board under the Opium Convention was deferred for another year on financial grounds, and other credits for useful pieces of international work were refused. Many hours were spent by financial experts of all the nations, from Albania to Venezuela, in scrutinizing the modest budget of the League as though it were the budget of a small State with already an intolerable burden of taxation, when the fact is that the League of Nations adds scarcely a featherweight to the taxation in any country. The total annual cost of the League, including the general services of the secretariat, the special organizations, the International Labour Office, and the Permanent Court of International Justice, is some 24 million Swiss francs or, say, a million pounds in English money, and the cost is spread over fifty nations. The cost of the Health Organization, including the Lepidemiological Service, is less than £40,000, the supervision of the opium traffic and other social activities cost less than £11,000, while intellectual co-operation is purchased for even a smaller sum. It is true that these special activities are not in the main line of the League's purpose, but they are, as one distinguished statesman after another has declared at the recent assembly, most powerful auxiliaries for peace and "moral disarmament." Take intellectual co-operation—the "baby" of the League's activities. Its centre is the international institute recently created in Paris as a gift to the League from the French Government, which also affords a large sum for its maintenance, though Austria, Czechoslovakia, Hungary, Italy, Poland, Switzerland, and other States, not forgetting Monaco, make grants for this work. The work consists in the promotion of co-operation between States by exchange of publications, collaboration of libraries and museums, interchange of professors and students, the preparation of scientific bibliographies—biology is at present in hand—and annual tables of constants and mathematical quantities, and the endeavour to place intellectual rights on a secure footing. Under this last head two questions in particular have claimed attention—namely, scientific property, and improvements in the existing convention on

copyright. All is ready for the summoning of a committee of experts on the former subject with a view to the conclusion of an international convention to protect and reward scientists and their discoveries. Such work as this has to run the gauntlet of aiggardly economy, and financial questions alone prevent it from being more vigorously pursued. The spirit of peace and goodwill in the world has to be paid for. Its price is a minute fraction of the price of war, but it is not to be had for nothing. Our correspondent adds that no one has made a better impression on the Assembly than a medical member of the British Parliament, Dr. Walter Elliot, Parliamentary Under-Secretary, Scottish Office, whose utterances, both in the Assembly itself and in the various Commissions, have gained him the ear of the men of many nations in quite an unusual way. Dr. Elliot has been one of the three substitute delegates in the British delegation, the others being Dame Edith Lyttelton and the Right Hon. Sir Edward Hilton Young.

### DERMATOLOGY AND VENEREOLOGY IN GERMANY

THE fifteenth congress of the German Dermatological Society was held in Bonn on September 4th, 5th, and 6th. The membership of the society is now over 800, 550 were present at the congress, including 65 dermatologists from outside Germany. The meetings were held in the Beethoven-Halle, and the proceedings were formally opened by Professor Riehl of Vienna. Speeches of welcome were delivered by the rector of Bonn University, representatives of the German Government and of medical practitioners in Bonn, and by Professor Erich Hoffmann, who acted as chairman throughout the proceedings. As the meeting was held in the Beethoven-Halle it was thought fit to celebrate the centenary of the musician's birth by a selection from his works. Actually 115 papers were on the programme, but although the meetings began at 9 a.m. and ended at 6 p.m. some could not be read owing to lack of time. Except for the opening of the set discussions the allotted time for each speaker was ten minutes. The authors were asked to speak from notes and not to read their papers, but unfortunately most speakers did not comply, and owing to the brief time available the contributions were delivered rapidly and were difficult to follow. A discussion on the biological and pathological aspects of the action of x-rays was opened by Professor L. Grebe (Bonn), followed by Professor Hans Meyer (Bremen) and Dr. G. Miescher (Zurich). The remainder of the first day was devoted to papers relating to the same subject, to the Bucky or "Grenz" ray, and to ultra-violet irradiation. The "Bucky ray," which has a wave length intermediate between that of ultra-violet light and x-rays, is obtained by means of a modified x-ray tube and a specially wound high tension transformer, producing voltages lower than 10 kilovolts. The advantages claimed for this wave length are that it is absorbed by the superficial layers of the skin without damaging the germinative layers, thus giving greater safety and avoiding the permanent changes in the skin which follow repeated x-ray exposures. This form of irradiation has evidently aroused much interest in Germany, but there is by no means unanimity as to its practical value. The following day was devoted to papers on syphilis and gonorrhoea in the morning, and to general dermatology in the afternoon. For obtaining cerebro-spinal fluid for purpose of examination in cases of syphilis, the suboccipital route instead of the lumbar puncture was strongly advocated by the members of the Bonn dermatological clinic. The advantages claimed are the complete absence of headache following the procedure, thus allowing the operation to be carried out in the out-patient department. This somewhat formidable method has been adopted as the routine in the clinic,

and over 1,000 such examinations have been performed. On the other hand, there were two papers extolling the fine needle for subcutaneous lumbar puncture examinations. Malaria therapy is evidently much in vogue, and was even advocated for resistant gonorrhoea in women. Papers on general dermatology were of great variety, embracing amongst other subjects the pathology of the skin, the dermatovascular, cosmetic operations, and the treatment of eczema by the Störin van Leeuwen chamber. At the close of the meeting eighty patients were shown, many of whom had been collected from distant parts of Germany. The members had the opportunity of visiting the Bonn skin clinic, which is a two-story building containing 150 beds reserved for patients suffering from skin or venereal disease. It is under the charge of Professor I. Hoffmann, who has five paid assistants. In addition to the wards the building contains a series of out-patient rooms, a demonstration theatre, photographic room, a well equipped x-ray and light department, a large library of dermatological literature, cabinets containing 800 wax models of common and rare skin diseases, research laboratories and animal houses. Reviewed as a whole the impressions obtained from the meeting was that in Germany there is great activity and painstaking research by the junior dermatologists in many of the towns, they are stimulated and guided by senior men, who appear to have sufficient funds at their disposal to provide the necessary equipment. Dermatology is evidently considered an important branch of clinical medicine for each student must attend lectures and demonstrations for six hours each week during two terms. Wax models are used extensively for teaching purposes, one clinic alone is said to possess a collection of 4,000

education, and research, (4) the training of hospital executives, nurses and auxiliary personnel, and (5) the economic problem of hospital administration. It was also agreed that one session be devoted to the discussion of special problems, such as the care of the mentally ill and the comparability of hospital statistics. After Dr Dorre had thanked the meeting for the honour it had bestowed on his country and the American Hospital Association in giving them the privilege of entertaining the initial congress, Dr Sand congratulated all present on having taken a step which would not only serve the cause of the sick, but also that of international goodwill.

#### SUPERVISION OF FOOD IMPORTS

THE annual report of the medical officer of health for the Port of London, with its lists of the number of ships disinfected and the number of rats killed, is enlivened by descriptions of difficulties which arose in 1926 in regard to various imported foodstuffs. Thus we learn that in a consignment of canned lobster there were not only obviously blown cans with stinking contents, but also cans in which the strength of the tin masked early decomposition with gas formation. The decomposition could only be detected when gas escaped on puncture. The packers objected to destruction of the goods, all that was wanted, they said, was 'to give the goods a short water bath say twenty minutes and vent them and then stop them.' On this Dr Willoughby remarks that the proposal to 'vent' decomposing goods is primitive in the art of canning and outside consideration in the practice of public health. He released two cases to the Dominion Government concerned for its information and experiment. Some tins of cherries, preserved with the allowable sulphur dioxide, were found to emit on opening a strong smell of sulphuretted hydrogen. The smell evaporated in a few days, but to avoid the disgust of the private consumer on opening such a tin the consignment was released to a firm of manufacturers of delicacies on the understanding that they would air the cherries before using them. The process of airing was also applied to some meat which had become tainted by an atmosphere of oil fumes. Dr Willoughby tells us that domestic experiment was made from time to time to find out how the process of airing was proceeding. In the end the happy result was that it became possible to release the whole of the material without prejudice to the public. The experimental shipment of a cargo of chilled beef from Australia is described in the report. The difficulty in the process is to chill sufficiently to prevent the growth of moulds without freezing to such a degree as to destroy the muscle substance and cause a leak of sanious fluid on thawing. As cleanliness in a high degree is necessary in order to ship chilled meat over long distances, the consumer benefits and, as Dr Willoughby says, in this instance commerce and health run hand in hand.

#### THE IMPROVEMENT OF INNS

THE decrease in drunkenness in this country may be attributed to many causes—to trade depression, to the shortening of hours for licensed trade, to the high price of beer and spirits resulting from heavy taxation to the increase in amusements and outdoor sport, to the abolition since 1904 of 25,000 'redundant' licences, or to better education of the people in habits of sobriety. As an adjunct to all or any of the causes, the Central Public House Trust Association would like to add 'disinterested management.' The last annual report of the association records a very fair measure of success, notwithstanding the industrial troubles of 1926, so that many of the affiliated trusts have been able to pay their maximum dividend for the year. A number of the trusts, however,

#### AN INTERNATIONAL HOSPITAL CONGRESS IN 1929

ON September 19th, on the invitation of the American Hospital Association, representatives from eleven countries met at the League of Red Cross Societies, Paris, to discuss the organization of an international hospital congress. The British representatives were Mr J. Courtney Buchanan, Lieut.-Colonel Clement Cobbold, Mr W. H. Harper, and Captain J. E. Stone. Dr Rene Sand, technical counsellor to the League of Red Cross Societies, was unanimously elected chairman. Dr Joseph C. Doane, medical director of the Philadelphia General Hospital and president of the American Hospital Association, said that he and Dr Lewinski-Corwin (director, Hospital Information and Service Bureau, United Hospital Fund) had come in a very humble mood to meet the representatives of institutions which had been at work for centuries. Two years ago the Board of Trustees of the American Medical Association had appointed a Committee on International Hospital Relations, which had sent him and Dr Lewinski-Corwin to Europe with the mission to pave the way for an international hospital congress. The speakers who followed unanimously pledged the support of the countries and institutions they represented, and M. Queller, chief of the hospital service of the Public Assistance of Paris, promised a hearty welcome to the hundred institutions supported by the Public Assistance of Paris should it be decided to hold the congress in France. Invitations were also extended by the representatives of certain other countries, but at the conclusion of the meeting it was unanimously agreed that an international executive committee be set up to prepare an international hospital congress to be held in June 1929 in the United States. It was also agreed that the principal problems to be discussed at the initial congress should be limited to the following:—(1) the creation of national hospital associations and of an international hospital association, (2) the respective fields of public and private hospital work, (3) the hospital as a unit for cure and prevention of disease, medical

are fortunate in owning wayside inns in country districts, which have benefited by the enormous increase in motor traffic. The development of trusts is handicapped by the difficulty of raising capital upon which the return is strictly limited to a maximum, and by the licensing laws which base licence duty on alcoholic trade instead of on the value of the premises. So it comes about that improvements in the accommodation of the building are often penalized. In this connexion it is interesting to note that the main objects aimed at in a trust house, whether in designing a new building or adapting an old, are a convenient service from the lichen to the tea-room, dining-room, and tea-garden, and such arrangement of the bus and taproom that the manager can supervise both the customers and the bar attendants.

#### MEDICAL SOCIETY OF LONDON

THE programme has now been issued for the first half of the 155th session of the Medical Society of London. As usual, the society will meet on Monday evenings. On October 10th, after the annual general meeting, Mr H. W. Cusson will deliver his presidential address on "Surgery in the early days of the Medical Society of London." On October 24th Dr B. B. Vincent Lyon will open a discussion on the development of the duodenal tube and its practical value in diagnosis and treatment. November 14th is to be a clinical evening. On November 28th Mr T. P. Legg will introduce a discussion on the society's report on the late results of operation for carcinoma of the breast. Fellows wishing to take part can obtain copies of this report from the secretary. On December 12th a debate on insanity will be introduced by Dr Eustace Callender, followed by Dr Gordon Holmes and Sir Maurice Craig. The syllabus of the second half of the session will be published early in January. In the meanwhile it is notified that Dr F. J. Porvinton will give the Lettsomian Lectures, on February 20th and 29th and March 7th, on "Rheumatic heart disease," and that Sir Archibald Guird will deliver the Annual Oration, entitled "Lessons of rare maladies," on May 14th. As already announced in our columns, this year's David Lloyd Roberts Lecture, on "Criminal law and insanity," will be given by Lord Hewart on November 16th at 5 o'clock.

THE *Medical Officer* was founded in 1908 as a weekly journal for medical men in the Government and municipal services, under the able editorship of Mr G. S. Elliston, M.C., M.A., with the support and collaboration of public health officers. We congratulate our contemporary on reaching its 1,000th issue on Saturday last, September 24th, and wish it many more years of independent and useful life. Its editor, as many of our readers know, is a son of the late Dr W. A. Elliston, President of the British Medical Association in 1900, and a brother of Mr Guy Elliston, who was Financial Secretary and Business Manager of the Association from 1902 until his death in 1918.

THE HAUVERAN Oration before the Royal College of Physicians of London will be delivered by Sir William Hale-White, K.B.L., at the College, Pall Mall East, on Tuesday, October 18th, at 4 p.m.

WE regret to announce the death at Marseilles of Sir Peter Peck O'Connell, M.D., M.Ch., formerly senior surgeon to the Mater Infirmitum Hospital, Belfast.

THE Hauben gold medal of the Royal Institute of Public Health for 1926 has been awarded to Sir Ronald Ross in recognition of his eminent services to public health.

## THE BOARD OF CONTROL

### THIRTEENTH ANNUAL REPORT

DURING the past year interest in lunacy and mental disorder has been focused principally on the findings of the recent Royal Commission. Time did not permit of the Board of Control making a detailed examination of the recommendations of the Royal Commission in its last annual report, as the Royal Commission's report was published in July, 1926, and so special interest attaches to the Board's report for the year 1926, in virtue of the official pronouncement of its views on the Commission's recommendations. Whatever differences of opinion may exist in regard to a few of the recommendations, the report of the Royal Commission has, in the Board's opinion, been welcomed on all hands as a document of great value, and it is one which "throughout breathes a spirit of progress and humanity."

The immediate cause which led to the appointment of a Royal Commission was the uneasiness roused in the public mind by a number of charges, recklessly made, to the effect that large numbers of sane persons were being detained as insane, that the whole system of lunacy administration was wrong, and that widespread cruelty existed in public mental hospitals. In regard to these charges the Board notes with satisfaction that the Commission has spoken with no uncertain voice, and in repudiating them, has taken the opportunity of "paying a tribute to the skill, devotion, and self-sacrifice of the nursing staffs, who in circumstances peculiarly exacting are rendering great service to suffering humanity." Satisfaction is also expressed with the recommendations of the Commission on the subject of early treatment of mental disorder. Paragraph 45 of the Commission's report has this sentence—which the Board fully endorses—"Certification should be the last resort in treatment, not the prerequisite of treatment."

In giving evidence before the Commission, the Board of Control suggested that for the purpose of settling the procedure to be adopted for the reception of persons suffering from mental illness patients should be divided into three classes: voluntary, non-volitional, and unwilling.

As regards the voluntary class, the Board suggested that treatment without certification should be given in any mental hospital, public or private, or general hospital nursing home, or under private care, subject to certain provisos in regard to notification and medical reports. The Commission's recommendations followed along the same line.

As regards the non-volitional cases, the Board of Control suggested reception without certification, on the "recommendation" of two medical practitioners, into any mental hospital or suitable institution. The Commission, if it had been free to consider exclusively the medical treatment of the patient, would have had little difficulty in accepting this suggestion, but, notwithstanding its sympathy with the Board's proposals, deemed it necessary that treatment should only be given on the authority of a provisional order by a magistrate.

The Commission's expression of its desire that the law should be altered to ensure more effective protection to medical men and others in the bona fide discharge of their duties under the Lunacy Acts meets with the Board's entire concurrence.

The Board notes with satisfaction the recommendations made by the Royal Commission regarding the duties of medical superintendents that they should be relieved as far as possible of administrative details, and so devote the greater part of their time to medical questions which are more immediately their concern.

The Board endorses the statement of the Commission that the present medical staffs of some institutions ought to be enlarged, and welcomes the recommendation that systematic facilities should be given for assistant medical officers to proceed on leave for the purpose of post-graduate study, and that the staff should be sufficiently large.

Lunacy and Mental Disorder. Thirteenth Annual Report of the Board of Control for the year 1926. Part I. London: H.M.S.O. Office or through an bookseller 1927. 2s. net.

permit of this. The Board also supports the observation that, in order to attract and retain in the service suitable assistant medical officers, their financial prospects should be improved.

Entire agreement is also expressed with the Commission's recommendation that the treatment of insanity in all its stages should be divorced from the Poor Law. The Board considers that the present arrangement, under which patients are first dealt with in Poor Law institutions before reaching the mental hospitals, is open to grave objection. It is also deemed indelible that individuals should be paperized merely because they become ill mentally and are treated at the public expense.

#### Mental Disorder

On January 1st, 1927, the number of notified insane persons under care in England and Wales was 135,626, an increase of 2,745 during the preceding year while the average annual increase for the five years ending January 1st 1927, was 2,552. The relative distribution of the sexes—males 43.9, females 56.1—was the same as in each of the three preceding years.

First admissions—that is of certified patients—during 1926 numbered 17,517 or 79.9 per cent of all the direct admissions—about 1 per cent below the average of the preceding five years.

The number of persons discharged from reception orders as recovered, relieved, or not improved numbered 10,469 (males 4,279 females 6,181). Of these 6,983 were discharged as recovered, yielding a recovery rate, calculated upon the direct admissions of 31.85 per cent.

Deaths numbered 8,411 (males 4,131, females 4,280). This number was 140 fewer than in the preceding year and the death rate was the lowest ever recorded—7.3 per cent of the daily average number resident.

The question of accommodation has continued to give considerable anxiety. Quite apart from the actual growth of numbers additional buildings, especially admission hospitals and laboratories, are necessary for the more effectual treatment and classification of the patients.

#### Infectious Diseases

Euteric fever occurred in 33 mental hospitals in 1926 as against 35 in 1925. Thirteen hospitals had one case each and nine hospitals had two each. The disease terminated fatally in 10 men and 20 women patients and in 2 women nurses.

The number of cases of dysentery during the year was 515—more than double the number for 1925. The deaths, which numbered 98, were, however, only 19 in excess of those in 1925. The infection occurred in 52 hospitals, and three hospitals together accounted for 212 cases.

In spite of the increase of 2,710 in the hospitals' population in 1926 the number of notifications of new cases of tuberculosis (all forms) fell by 195, and the number of deaths diminished by 43. The rate per 1,000 of notifications of pulmonary tuberculosis for the year was 8.4 the death rate was 6.6—nearly the lowest yet recorded.

#### Mental Deficiency

The lack of accommodation for defectives becomes every year more urgent. The Board directs attention to its report of the previous year, when this subject was fully dealt with, and also to the Report of the Departmental Committee on the Treatment of Young Offenders whose opinion must carry weight with those local authorities who have made no provision for the mentally defective.

The number of mentally defective patients on January 1st 1927 was 38,852 (males 19,144, females 19,738). This total includes cases under statutory supervision. During the year there was a total increase of 2,667 patients under care.

Reprehensible as is the marriage of defectives who have been certified as unable to manage themselves and their affairs or as needing care, supervision and control it is by no means unknown but the Board whilst characterizing the practice as the height of unreason and the negation of the aims of a civilized community seriously doubts if public opinion is sufficiently informed to allow of the necessary legislative measures to be taken to prevent it.

It is pointed out that the procreation of children by

unmarried defectives, denorable as it is, has not as a rule the same evil consequences to the children as the marriage of defectives. In the former case the children are generally brought up apart from their parents and so given the chance of as full a development as possible, whilst those who are the offspring of married defectives remain under the control of persons who are incapable of taking care of them, and they are consequently exposed to hardships, neglect, and ill treatment that the mental condition or their parents renders inevitable.

The Board is of opinion that the publication of the facts discovered by local authorities as to the extent to which marriage or defecation takes place might go far to prepare the way for legislation and to justify an alteration of the law.

With regard to the bill recently introduced into Parliament to amend the Mental Deficiency Act of 1913 in respect chiefly of the definitions in that Act, the Board expresses thorough approval. The present definitions, which require that only those defectives may be dealt with in whom it can be proved that the defect has existed "from birth or from an early age" have prevented many cases from receiving the care and protection of the Act although urgently in need of them.

## THE NEW NATIONAL LIFE TABLE

### REPORT BY THE GOVERNMENT ACTUARY

A REPORT BY THE GOVERNMENT ACTUARY Sir Alfred W. Watson, K.C.B. on life tables based on the population of England and Wales as returned in the 1921 census and on the average number of the deaths recorded in the three years 1920, 1921, and 1922 has been published as Part I of the Registrar General's Decennial Supplement. Throughout the report the experience of males and females has been examined separately.

The principal table is a new national life table for England and Wales, henceforth to be known as the English Life Table No. 9. This table confirms the generally accepted view that the vitality of the nation (as measured by length of days) has been steadily improving.

A rough measure of the improvement is afforded by the following comparison of the expectations of life: the English life tables No. 7, No. 8, and No. 9 being taken as representative of the conditions existing in 1906, 1911, and 1921 respectively.

#### Expectation of Life Years

MALES				FEMALES			
Age	Engl. h. Life Table No. 7	Engl. h. Life Table No. 8	Engl. h. Life Table No. 9	Age	Engl. h. Life Table No. 7	Engl. h. Life Table No. 8	Engl. h. Life Table No. 9
0	43.43	51.59	56.62	0	52.43	56.35	59.58
10	51.81	53.68	56.67	10	54.53	56.91	57.53
20	43.01	47.21	45.73	20	45.77	47.10	47.75
30	37.75	36.81	37.40	30	37.36	35.57	40.25
40	27.46	27.7	9.19	40	29.37	30.50	31.26
50	17.70	20.29	21.56	50	21.81	22.51	23.69
60	11.49	13.18	13.36	60	15.01	15.4	16.22
70	8.49	8.53	8.75	70	9.25	9.3	9.55
80	4.8	4.90	4.93	80	5.20	5.43	5.5
90	2.50	2.87	2.82	90	2.94	3.10	3.15

Examination of the rates of mortality at individual ages shows that the improvement is especially marked at the youngest ages. The probability of a child dying in the first year of age is found to have decreased by about 40 per cent during the fifteen years from 1906 to 1921.

At the ages of adolescence and of young manhood and womanhood the new rates do not differ greatly from those on the No. 8 table. In the case of males there is no

<sup>1</sup> The Registrar General's Decennial Supplement, England and Wales 1921, Part I, Life Table. H.M. Stationery Office. (Price 2s.)

evidence of any deterioration, but it is noteworthy that for females aged between 18 and 27 the new rates of mortality are appreciably higher than those in the previous national table. In the main part of the table from ages 30 to 80 the vitality of both sexes is shown to have increased very considerably, but at the advanced ages little progress is indicated.

Rates of mortality have been calculated for women with reference to marital condition—single, married, and widowed. At the youngest ages for which comparison is possible the lightest rates are those for single women. The rates for single and married women differ but slightly between ages 24 and 37. Thereafter the rates for married women are usually lower than those of single women or widows. The rates of mortality for widows are invariably heavier than those for single women or wives.

The deterioration in the vitality of young women between 18 and 27 disclosed in the national table reappears in the spinsters' experience, but is not found in that of married women.

A special feature of the report is an investigation of the comparative mortality experience of sections of the country, according to geographical situation and density of population. For the purpose of this inquiry the country has been divided into ten geographical areas. Each of these, except Greater London, has been subdivided into three sections—county boroughs, urban districts (including municipal boroughs), and rural districts—and the experience of each section has been examined in various age groups. The results of this investigation are summarized in the following table.

*Ratios of Population Death Rates in the several Geographical Divisions and Subdivisions to the corresponding Rates for England and Wales (ages 5 and upwards) computed throughout on a Standard Age Distribution—namely, Population of England and Wales, Census 1921*

Geo-graphical Division	MALES				FEMALES			
	County Boroughs	Urban Districts	Rural Districts	Whole Division	County Boroughs	Urban Districts	Rural Districts	Whole Division
Northumberland and Durham	1.29	1.13	0.94	1.14	1.28	1.23	1.14	1.23
Cheshire and Lancashire	1.25	1.10	0.89	1.17	1.21	1.15	0.98	1.17
York (West Riding)	1.18	1.06	0.91	1.10	1.17	1.10	1.01	1.12
South Wales	1.15	1.10	0.93	1.07	1.14	1.20	1.09	1.16
York (East Riding North Riding) etc.	1.17	0.97	0.79	0.98	1.18	0.99	0.91	1.02
North and West Wales	—	0.95	0.95	0.95	—	0.95	1.03	1.03
Central Counties	1.05	0.93	0.81	0.94	1.02	0.95	0.88	0.95
Southern Counties	0.93	0.86	0.77	0.84	0.89	0.83	0.82	0.84
Eastern Counties	0.91	0.86	0.73	0.81	0.90	0.86	0.83	0.85
Metropolitan Area	—	—	—	1.03	—	—	—	0.96

It appears to be established that the rate of mortality varies both with the geographical distribution of the people and with the density of the population, and that greater variation in the death rate from the general average is attributable to the geographical element than to density of population.

In all the areas the difference between the death rate of the county boroughs and that of the rural districts is greater among males than among females. The diversity of the experience of the two sexes appears to be attributable not to the greater strain of occupational conditions as affecting male lives in the county boroughs, but to the relatively favourable mortality experience of the male population in the rural areas.

A detailed investigation has been made of the experience of the sections showing the highest and lowest death rates—the county boroughs of Northumberland and Durham, and the rural districts of the Eastern Counties—to illustrate the maximum effects of the geographical and density elements. The results of the comparison are very striking. For example the probability of a child dying within the first ten years of its life in the rural districts of the

Eastern Counties is only about half of that in the county boroughs of Northumberland and Durham. The respective probabilities of dying within ten years in the county boroughs of Northumberland and Durham and in the rural districts of the Eastern Counties are

For a man aged 20	0.052 and 0.034
" " 50	0.201 and 0.104
" " 70	0.711 and 0.535
For a woman aged 20	0.042 and 0.036
" " 50	0.159 and 0.095
" " 70	0.622 and 0.463

The effects of density of population were further investigated in the case of one area, the Central Counties.

For Greater London complete life tables, for males and females separately, have been prepared. A general survey of the experience indicates that the vitality of the metropolitan area approximates fairly closely to that of England and Wales, that of the males being slightly inferior and that of the females slightly superior to the general average. In the case of both sexes the rates of mortality for ages between 15 and 30 are found to be relatively light, a feature traceable in the experience of other populous sections, and attributable presumably to the fact that the population of the towns is being continuously recruited by the accession of healthy lives from other districts. It is suggested that the demand for domestic help may account for the fact that the fertility is more strongly marked amongst women than amongst men.

In conclusion, it must be emphasized that the rates of mortality shown in the national tables are the results of the aggregation of data relating to a number of sections with widely varying characteristics, and that the circumstances of any one particular area may not be at all accurately reflected at any point in the general experience to which it has contributed.

## MEDICAL DEFENCE UNION

### ANNUAL GENERAL MEETING

THE annual general meeting of the Medical Defence Union was held at the Royal Bath Hospital, Harrogate, on September 24th, with Sir HERBERT WATERHOUSE, the president, in the chair.

In proposing the adoption of the annual report of the council for the year 1926-27 Sir Herbert Waterhouse said that this was a record of the continued growth and progress of the Union, though limitations of space made it only possible to mention some of the more important matters dealt with during the past year. The Hume Spry case was the biggest and the most anxious case with which the council had been concerned during the year, it was also the most expensive, and, he believed, had cost more than any other action since the Union was founded. Fortunately, however, the members concerned were completely vindicated. Commenting on the case the president entered a protest against the existing judicial system which permitted medical practitioners, who had done their duty honestly in the interests of the public and of the patient, "to be subjected to a lengthy and costly trial because the plaintiff is able to produce affidavits from medical men who see him some months or even years after he was certified, testifying without any inquiry of those professional attendance on the patient at the time of, or prior to, certification that he was not insane when certified, and that those who certified acted negligently and/or in bad faith. Except for such affidavits this case would never have gone to trial. The verdict of the jury and the remarks of the judge sufficiently indicate the value they attached to such evidence."

In numerous other cases the president continued the Union had been able successfully to defend members whose professional work had been called in question. As a consequence of the satisfactory state of its finances the Union had been able to increase still further the benefits of membership. The council was now prepared to defend an action brought against a member in consequence of the acts or omissions in any case of a subordinate medical officer or a non-medical sub-editor and of a partner or assistant if he belonged to either of the two English defence societies. This constituted a material advance on the former position, and there was further innovation. A member could now obtain protection

against actions arising out of the acts or omissions of an assistant who was not himself a member of any defence society by paying an additional annual subscription of 10 in advance. Again, the Union's reciprocal arrangement with the other society as regards assistants had now been extended to partners.

Referring to a circular letter issued last February to every member of the Union on the subject of x-ray examinations in cases of injury to bones or joints the president said that this had been interpreted by some as implying that a member who had not made an x-ray examination in any such case would not be defended. That was not what the letter said, and it was not what the council intended. It was a warning that in all such cases the member should in his own interests advise an x-ray examination and that when such advice was not followed the member should for his own protection place the advice given on record by writing a letter to the patient and keeping a copy to ease of future trouble. This recommendation was based on experience of scores of cases, but was constantly ignored, thus depriving the council of the only evidence which as a rule made a successful defence possible.

Sir Herbert Waterhouse concluded by expressing appreciation of the services of Dr. James Neal, the general secretary, and Mr. Hemp on the solicitor.

The report of the council and the financial statement for the year 1926 were adopted unanimously. Dr. E. C. Greenwood, Dr. H. Robinson and Mr. W. G. Spencer, the retiring members of council were re-elected. The auditor, Mr. Lewis Hardy, was reappointed, and authority was given for the payment of the first class railway fares (with expenses if detained for the night) of members of the council attending council meetings from provincial centres. The proceedings ended with a vote of thanks to the president and council for their services during the past year.

## Canada.

[FROM OUR MONTREAL CORRESPONDENT]

### MENTAL AND PHYSICAL DEFECT

ALBERTA is the first Canadian Province to venture on legislation in regard to sexual sterilization. The criticism made at the outset, however, is that the measure proposed is not as far reaching as has been generally advocated, since it is designed to apply only to persons who have been inmates of a mental hospital. This will obviously result in a large number of feeble minded not being reached at all, whilst on the other hand many such inmates suffer from mental disease rather than mental deficiency. The administration of the Act is to be entrusted to a board of two medical practitioners nominated by the University of Alberta and the Council of the College of Physicians and Surgeons and "some person other than a medical practitioner." The three appointments are to be made by an order in council. Some criticism of the Provincial Government is also being made in regard to a travelling clinic which the department of public health has been sending to certain outlying districts where there is a lack of medical attention, and where it has been found on investigation that there are amongst the children remediable physical defect. This type of clinic has been in operation for some years, apparently successfully, but the extension of its work to larger areas is, in the opinion of some, apt to introduce an element of interference with ordinary medical practice. On the other hand, the Province claims that there is no intention of introducing any form of State medicine, but rather to provide medical aid in areas where it does not at present exist, or is at any rate inadequate in amount. It is claimed by the critics, however, that no co-operation with the medical men is being attempted. The work is done entirely through the schools (children only are treated) the parents being notified of the date the clinic is to arrive. The collection of the clinic fees is made by a local committee chosen from groups of schools. There also seems to be ground for criticism in that there is no adequate provision for the after-care of the children in such cases, for example, as the removal of the tonsils and adenoids.

### MEDICINE AND THE STATE

The question of State medicine has been brought before the profession in Canada as the result of a letter from a physician in Saskatchewan. This Province is one in which the population is spread over very large areas and medical service is not proportionately arranged. The Provincial Government has therefore seen fit to appoint salaried medical officers in certain areas. It appears, however, that State paid doctors were appointed in two municipalities which had no real need for them, and the medical men already established there felt appreciably affected. Expressions of opinion on the subject of employment of doctors by the State have been obtained from the various Provinces, and they show decided variations in the point of view. On the whole, the principle of municipal doctors for general medical work was objected to. It was admitted, however, that the distinction between contract work with the Government and contract work with companies is one which is hard to draw, and there never has been any criticism of companies employing medical men. It was hinted, too, by some that these State appointments were an expression of discontent on the part of the public with the excessive cost of sick attendance, in some parts of the country at least. This, of course, introduces another question altogether. It is quite possible that these rumblings, however faint at present, may be warnings of what the profession may have to face in its future relations with the political forces.

### THE MEDICAL SCHOOLS

There is no falling off in the numbers of entrants for the medical schools, judging by the applications received by the McGill Medical Faculty this year. Over 600 have made application, but only 120 of these have been accepted for the first year class owing to the recent decision to keep the entrance classes within reasonably handled numbers for teaching. It is remarked that a noticeable proportion of those entering medicine are the sons of physicians. About fifty students are from the United States, there being representatives from sixteen States. This is perhaps one of the more healthy forms of "peaceful penetration," providing as it does a very thorough form of mutual understanding. California seems to be unusually eager to send its sons abroad—and to Canada—since a large number of applications were received from that State six of which were accepted. It augurs well for the general educational standing of the medical men of the day that about 75 per cent of those coming in are taking B.A. or B.Sc. degrees before entrance.

### THE CANADIAN MEDICAL ASSOCIATION

The annual meeting of the Canadian Medical Association is now a good way behind us, but it has left a lasting sense of growth and expansion within the profession in Canada. It was held in Toronto, and while it would be an invidious comparison to say that it was any more successful than previous meetings, there is no doubt that it had the largest attendance yet chronicled. Since this was a jubilee year for the Canadian Medical Association Dr. Starr took the opportunity of recalling its progress since its foundation in 1867. There had been striking growth, but there were periods of depression. In 1892, for example, there seemed to be such a lack of interest on the part of the members that a proposition to disband was seriously considered. The contrast between such an outlook and the present strength of the association needs little elaboration. There is a national value in these conferences which must not be overlooked. We have an East and a West and a Middle West, too, in Canada, and, as it was well put by one member, "the country needs being together from East to West, and every social contact, every common interest, every intellectual affinity, every mental picture of the face of a friend afar, every idea gathered from someone who lives at the other side of the Dominion, is at the same time a couplet between the country's sections and a buffer between its sectionalisms." The meeting in 1928 will be held in Charlottetown, Prince Edward Island.

# Union of South Africa.

[FROM OUR PRETORIA CORRESPONDENT]

## TUBERCULOSIS RESEARCH

THE South African Institute for Medical Research, Johannesburg, has undertaken a comprehensive investigation into the causes, mode of spread, and methods of prevention of tuberculosis in the Union. The investigation is being financed in equal shares by the Chamber of Mines, the Department of Public Health, and the Native Deferred Pay Fund Board, and an advisory committee has been appointed on which all the parties concerned are represented. This research is being led by Colonel Lyle Cummins, professor of tuberculosis in the Welsh National School of Medicine, Cardiff, a well known authority on the subject, who is being assisted by Dr Peter Allan, late medical superintendent of the tuberculosis sanatorium of the Union Health Department at Nelspoort. Professor Cummins is devoting the long vacations during the next three years to this investigation. He arrived in Capetown on July 25th, and proceeded direct by the "Union Express" to Johannesburg, where he was joined by Dr Allan, who has been seconded from the Health Department for the research.

As regards natives, the scheme involves investigations, not only of the labour centres on the Witwatersrand gold mines and of the collieries and diamond mines, but also in huts and locations in the native territories. The investigators have now completed a preliminary tour of the native territories of the Transkei and Ciskei, in which they were accompanied by Dr A. I. Girdwood, chief medical officer of the Witwatersrand Native Labour Association.

## HOOKWORM IN THE GOLD MINES

Reference was made in the BRITISH MEDICAL JOURNAL of June 11th to the discovery of an unexpected prevalence of ankylostomiasis among Rand native miners recruited from Portuguese East Africa. The investigations which followed have not only confirmed this discovery, but also that the disease has spread to British South African natives and even Europeans employed in the mines. All European miners on the Witwatersrand pass through the Miners' Phthisis Medical Bureau once in six months. This procedure is designed primarily to detect and eliminate early silicosis, but it serves sometimes also to detect other conditions. It was at the bureau that European hookworm cases were discovered at the end of last year, after the sanitation department of the Rand Mines, Limited, had drawn attention to the existence of the disease among mine natives. Thereafter miners coming to the bureau who were observed to be suffering from marked anaemia were advised to consult their private doctors, it being pointed out to them that the condition might be due to ankylostomiasis. Of 66 men so advised, at least 26 were since found to be suffering from hookworm disease.

It now appears to be certain that hookworm is contracted to the mines almost exclusively by natives from the East Coast (Portuguese East Africa), some 50 per cent of whom have been found to be infected on arrival. Infection of the underground workings has been traced in all of the mines investigated, and it is clear that most, if not all, of the infected Europeans have contracted the condition from these mines. Seventy-six European cases have been reported from mines known to have soil infection. Except at the Village Deep and City Deep, the infection of the workings seems to have occurred only during the last twelve or eighteen months, and does not appear to be serious. There is no evidence that Europeans can contract the disease anywhere in the Union outside the gold mines in which hitherto have been found. Hookworm amongst Europeans must therefore be considered an occupational disease. The Chamber of Mines has now accepted responsibility for the disease amongst Europeans as an occupational disease and has not only taken steps for its eradication but is also dealing with affected cases in terms of the Workmen's Compensation Act. The Rand Mutual Assurance Company, Limited, will pay compensation for such period as the workman is medically certified to be

incapacitated for work, this will usually be for the four two-day periods in which he is receiving active treatment. No additional charge is being made by the company for this insurance.

In natives ankylostomiasis is not being regarded as an occupational disease, as they arrive at the mine in an infected condition. All newly recruited East Coast natives now receive mass treatment with carbon tetrachloride prior to and during the period of their employment. All natives admitted to hospital for any cause on the Village Deep and City Deep are examined for the presence of hookworm, and all those found infected are treated. Even in untreated cases the worms tend to die out in six to nine months, provided there is no reinfection. This natural termination, and the fact that treatment is simple and efficacious, will make eradication a fairly easy matter, the worm will have to be eliminated from its native carriers and the infection of soil prevented by the adoption of suitable hygienic measures. Destruction of the larvae in the soil by means of antiseptic has not proved successful, but they are destroyed by saturating the soil with common salt solution.

## CONTROL OF CARRIERS OF INFECTIOUS DISEASE

In the *Government Gazette* of August 12th were published regulations with regard to carriers of infectious disease made under the Union Public Health Act. Persons suspected on reasonable grounds of harbouring infection, and consequently being liable to cause the spread of disease, must afford health officers of local authorities or of the Government every facility for obtaining specimens of blood, excreta, discharges, or of other material required for examination and investigation. A suspected carrier may be taken to a hospital or other suitable place for the purpose of examination and detained there as long as required. A carrier must observe all reasonably practicable instructions given him by a local authority or Government health officer in regard to disposal of his excreta and other precautions for preventing the spread of infection. He must notify change of residence or work. He may be required to undergo treatment, to remain under medical surveillance for a specified period, to report at specified times and places, not to handle food or articles used in connexion with food intended for consumption by others. Magistrates and health officers must ensure that these regulations are carried out sympathetically and without more hardship than is unavoidable in the public interest. Penalties are provided for persons found guilty of contravening these regulations, or failing to comply with them or to assist in their enforcement.

## THE LATE DR J. M. MEHLISS

The death occurred, on July 30th, in the Johannesburg General Hospital, of Dr John Maximilian Mehliß, in his fifty-ninth year. Since 1893 until shortly before his death Dr Mehliß was medical officer to the Lazaretto and the Chronic Sick Home at Rietfontein. These two institutions—the former a Union Government concern administered by the Union Health Department, the latter falling under the Transvaal Provincial Administration—are situated close together, between Pretoria and Johannesburg. The son of an officer of the King's Hanoverian Legion, which corps provided the Eastern Province of the old Cape Colony with so many of its finest settlers, Dr Mehliß was born in Grahamstown in 1868. His early education he received in Dalo College, King Williamstown, where he was a contemporary of the fathers of several of the younger medical practitioners of the Union of to-day. He went to Germany for his medical training, passing the Staats Examens in 1892, and receiving the Munich Doctorate the following year. He then returned to South Africa and after a short appointment as district surgeon of King'sdorp commenced the appointment at Rietfontein, which he held with conspicuous success. Last February cerebral thrombosis occurred, and it seemed unlikely that he would be able to resume his duties. But after a surprisingly short time he was about again, doing his daily rounds of the wards, conducting the venereal clinics and doing the minor operations as before. Though his movements were

and weak there appeared to be no mental impairment except for one curious manifestation: he would misbehave young practitioners for their fathers, and, somewhat to their embarrassment, discuss with them events that occurred before they were born. His will required a burial at Rietonin similar to that of his pauper patients of the Chronic Sick Home.

#### RETIREMENT OF DR. L. G. HAYDON

Dr. L. G. Haydon, assistant health officer for the Union of South Africa, retired from the Department of Public Health at the beginning of September after twenty-seven years in the service of the State. He qualified in Aberdeen in 1886, took the D.P.H. of the same University in the following year, and shortly afterwards volunteered for plague duty in India. He was soon in charge of seven improvised hospitals in a district where the average daily death rate was 350. As each hospital was always full at night, and all the patients usually dead before dawn, there was little to do in the morning but have the corpses burnt and the hospitals swept out. After plague had diminished in India, his loving spirit took him to Australia. He carried with him some plague cultures, and though on arrival in Victoria he gave specimens to the health authorities, he was arrested for importing dangerous material. However, the Victorian Government relented and he was put in charge of a leper station, but soon after we find him in Durban with Buller's forces helping with the wounded from Colenso. At the end of the Anglo-Boer war he entered the Natal public health service, with which he remained until the Union Public Health Act of 1919 established a central health department for the whole Union. During the great war he served in the African campaign. On September 2nd, the day he retired, he was bidden farewell by the staff of the public health department. Sir Edward Thoinston, in making a presentation on behalf of the staff, commented on the valuable services that had been rendered to the country by Dr. Haydon. The latter responded suitably, stressing particularly the splendid team work and loyalty in the department. He leaves shortly for Australia, where he has farming interests.

### Ireland.

#### CARNEGIE WELFARE CLINIC FOR DUBLIN

In the presence of a large gathering of the medical profession and ladies interested in philanthropic work in the city, the new Carnegie Welfare Clinic, Lord Edward Street, Dublin, was recently opened by Sir Donald MacAlister, Bt., K.C.B., vice-chairman of the Carnegie United Kingdom Trust in connexion with Civic Week celebrations. General Mileray, Minister for Local Government and Public Health, who presided, extended a hearty welcome on behalf of the citizens of Dublin to Sir Donald, who he said as President of the Medical Council had done so much to establish good relations between the medical profession of the Saorstát and of Britain. As vice-chairman of the Carnegie Trust he had given a great personal contribution of service to Dublin in seeing that the grant for that magnificent clinic had been preserved until the building could be erected. They were under a deep debt of gratitude to him for this, and for his presence. Sir Donald MacAlister, in declaring the institute open, said that ten years previously, in October, 1917, the Physical Welfare Committee of the Carnegie Trust decided to employ part of its funds for the purpose of encouraging the more and to promote better conditions of life for the needy mothers and infants of Great Britain and Ireland. Progress had been initiated and fostered here and there by various voluntary societies and local authorities. Yet, although the objectives of the movement were clearly of national importance, and concerned the well-being of the people everywhere, and though laws had been made empowering local expenditure on schemes for promoting its ideals, but little was being done in the country generally, to use the powers so to establish permanent agencies for the welfare of mothers and young children particularly. The policy of the Carnegie Trust in such cases was to apply its funds, not to relieve authorities of their obligations,

but by example to show them how they might best fulfil these. The Trust was willing to act as a pioneer in certain selected areas by offering, for instance, the capital cost of a suitable building for a new institution, where lack of capital was proving a hindrance on condition that the annual maintenance costs of the work in it were guaranteed from local sources. It sought to help those who were ready to help themselves when initial difficulties of site and building had been overcome. With this end in view it had decided to offer to each of half a dozen local authorities in England, Scotland, and Ireland the gift of a model maternity centre, designed and equipped on the best and most practical lines, provided that these authorities undertook its upkeep and agreed to work it efficiently for the purpose in view. Many more such centres were, of course, required if the needs of the people were to be adequately met, but the model centres would, if successful at least afford an example which might move other authorities to emulation and imitation, and so serve to advance the national solution of the problem. The Trust's enterprise, and the hopes it formed, had not failed of fulfilment. The Carnegie model centres in Shoreditch, Birmingham, Liverpool, Motherwell near Glasgow, and at Rhondda in South Wales had been of undoubted value to these places, but, what was more important, they had been copied—perhaps surpassed—in well over three hundred other localities. It could now be said that in Great Britain the movement had at last taken firm root. The immense public utility of the maternal welfare centre had been demonstrated and recognized. A new sense of responsibility for the well-being of the present generation had been awakened in the community, and the scope of the national public health service had been widened and made more humane in its treatment of mothers and infants than ever before. The aim of the centre was not treatment of damage already done, that was the function of hospitals and infirmaries. It was the prevention of damage, the conservation of life by the diffusion of knowledge among mothers, the watchful avoidance of danger to the normal, and the healthy development of infants. On behalf of the Trust he thanked Sir Coey Bigger for his aid to the Welfare Committee in realizing its aims and overcoming its difficulties. He had more than once proved a sagacious counsellor and a tactful negotiator. Gratitude was expressed also to Commissioner Dr. Dwyer, Dr. Russell, medical officer of health of the city, and to the architects and builders. Senator Sir Edward Coey Bigger, M.D., moving a vote of thanks to Sir Donald MacAlister, expressed the hope that his valuable address would be an inspiration to all interested in child welfare work. Sir John William Moore, seconding the vote of thanks, said that Sir Donald MacAlister had protected the medical profession from ruin in Ireland. It was by his statesmanship that the authorities on both sides of the channel had been brought to see that the Medical Acts would not be interfered with and that the Saorstát should have its own Medical Council and its own *Medical Register*. The vote of thanks was passed with acclamation, and Sir Donald was presented with a silver key as a memento of the occasion.

#### THE ETIOLOGY OF EPIDEMIC ENCEPHALITIS

SIR—Might I be allowed to point out that Dr. Greenfield's criticism in the *BRITISH MEDICAL JOURNAL* of September 24th (p. 535) of some of the work done on the etiology of encephalitis lethargica is hardly in agreement with the facts. He groups the workers in this country with Loewy and Strauss and Kling and then states that the results can be completely discounted. This statement is apparently based on the fact that rabbits suffer from a spontaneous form of encephalitis due to the *Freyfalkitoxon cuniculi*.

The main facts of our experimental work on encephalitis lethargica are that during the height of the first epidemic in England inoculations into monkeys and rabbits gave numerous successful results, and in the case of the latter as high a figure as 70 per cent was reached, while

numerous control inoculations were without effect. Further, the lesions produced were indistinguishable from those of the human disease.

Dr Greenfield admits that these histological lesions are very similar to those of the human disease—"in particular foci of lymphocytic exudate and perivascular infiltration", whereas, as is well known, the spontaneous encephalitis of rabbits shows a vastly different type of histological picture, in which the parasite can readily be demonstrated. He also states that the animals show no symptoms, therefore he could not have read the account, given by us, of the experimental disease.

I might add that some time ago Flexner in America made a somewhat similar unconsidered criticism, but apparently Dr Greenfield had not seen my reply.

I think that the points raised above are sufficient to invalidate the criticism put forward by Dr Greenfield—I am, etc.,

Bland Sutton Institute of Pathology,  
Middlesex Hospital, Sept 27th

JAMES MCINTOSH

SIR,—From the second paragraph of his address on the pathology of epidemic encephalitis at the Annual Meeting of the British Medical Association (as reported in your issue of September 24th, p 535) Dr Greenfield does not appear to be fully cognizant of the recent account given by Kling of his work on this question.

Out of 204 rabbits inoculated with different strains of virus of human encephalitis, Kling found that 40, or about 20 per cent, showed the characteristic lesions. On the other hand, out of 160 non-infected rabbits, 10 of which had been kept associated with inoculated animals, none showed lesions. Therefore before concluding, from McCarty's finding of lesions in 55 per cent of the stock rabbits examined in New York, that Kling's conclusions are invalidated, it should be remembered that the occurrence of the disease "spontaneously" in rabbits varies greatly in different countries. Also in England it is met with apparently very seldom. The late Dr Dakino told me that he had never found an instance, and I believe Poirou has observed extremely few. I myself have only found one case, in a rabbit which had previously been used for experimental vaccinia. On the other hand, out of 14 rabbits up to the present inoculated with brain material—either given me by Kling, or from one of my own infected animals—4, or 28 per cent, showed the lesions.

Kling unfortunately does not give the actual number of his positive cases which showed the alleged parasite, *Encephalitozoon cuniculi*, but three of my positive cases showed these bodies (that is, 21 per cent of the total inoculated). Kling makes one very interesting and important statement. Where the histological changes appeared to be in an early stage none of the elements were to be found, they occurred in the more advanced stages, when degenerated and necrotic foci could be found. Kling concludes that the bodies are not protozoa, from which they differ also greatly as regards biological points. He regards them as reaction-products to an invisible microbe, which he compares with the Chlamydozoa. From my own observations I agree with him that the bodies are not living organisms. My own view is that they are reaction-products, a result of pathological change in the brain (and other organs) of the rabbit, which may at times be induced by more than one virus, including that of epidemic encephalitis, although this particular reaction-product is not produced in the human brain by that virus. The similarity of *Encephalitozoon* to certain stages of the negro bodies, another reaction-product to an invisible virus, is marked—I am, etc.,

September 1st 1927

#### OXYGEN IN ACUTE PNEUMONIA

SIR,—Many practitioners unable to be present at the Edinburgh meeting must have read with interest and profit Professor John Hay's introductory paper to the discussion in the Section of Medicine on the treatment of acute lobar pneumonia (JOURNAL, September 17th, p 477).

As winter approaches we general practitioners look forward with a certain amount of foreboding to the cases of

acute pneumonia with which we know we shall have to deal, and in which a small percentage of mortality is to be expected. Professor Hay places it 10 to 15 per cent. Our interest, however, must concentrate, not so much on the 10 or the 75 per cent who will survive "if allowed to do so," as on the remaining 10 to 15 per cent "whose chances of recovery will depend on the manner in which the case is handled."

Professor Hay excellently sums up the principles of treatment in terse and sensible phrases, but he leaves us a little vague as to some details of symptomatic treatment, especially the use of oxygen, which he calls "probably the best cardiac stimulant."

I think it is generally agreed that oxygen is useless in the later stages of pneumonia and that it should be given early. Professor Hay says, "at the first indication of cyanosis" (p 479) and continuously for an hour at a time. He adds that the funnel method is more or less futile and suggests nasal catheterization with blocking of the other nostril, although admitting that patients with pneumonia will "very rarely tolerate anything applied over the nose and mouth." The crux of the problem is "to get oxygen into the blood," and no method of inhalation can absolutely ensure that or enable us to measure the amount that is therapeutically of value.

It has been my practice for twenty years to inject oxygen subcutaneously as soon as I diagnose acute pneumonia. More than one instrument is available for the purpose, making it possible to regulate with precision the rate and the amount of injection. Surely this is the only way to ensure oxygenation of the blood, such comparatively large quantities as 300 to 500 c.c.m. injected into the outer aspect of the thigh or into the lumbar region being completely absorbed in twenty-four hours. The injection is painless and its effect is immediately seen in the lessened cyanosis of the patient.

Whether oxygen so used will further reduce the mortality of the 10 to 15 per cent "doomed from the first" is a question my experience is too limited to answer, but if it is to be given a fair chance and not condemned as in Osler, 4th edition (p 137), where we read that "it is doubtful whether the inhalation of oxygen in pneumonia is really beneficial, and the work of Lorrain Smith suggests indeed that it may under certain circumstances be positively harmful," then I think subcutaneous injection and not inhalation must be our method of choice—I am, etc.,

Glasgow Sept 19th

A I WARDEN

#### MINERS' NYSTAGMUS AND THE WORKMEN'S COMPENSATION ACT

SIR—The Compensation Act has now been in existence for twenty-one years, and no one of its many amendments or alterations has dealt with the essential causes that have led to the universal dissatisfaction which it has occasioned. These causes are two: (1) The disease is variable, all the employers and the workmen in Northumberland and Durham recognize the fact that the patients have good days and bad days. (2) It is universally admitted here that if a hewer has once acquired the disease it will assuredly recur on returning to hewing.

With regard to (1) I instance the following experience of my own:

I saw one man on three successive Thursdays at the infirmary, on each of these occasions he had persistent uncontrollable nystagmus and all the other signs and symptoms that indicate the disease. Four days after his last visit to the infirmary, on Monday, he came to be examined by me a reference to my report on his condition. He had no nystagmus whatever in daylight, no tremors, no rapid pulse and did not reel after stooping. I spent half an hour testing him in a dark room with only one dazzling little per lamp in the stooping position in the act of hewing, and asked him to put him off into any position that would bring on his symptoms. He was quite unable to do so and said he felt quite fit on that day. He only complained of a little giddiness after prolonged stooping, which passed off almost immediately when he held him self erect. On the following Saturday he showed persistent uncontrollable nystagmus in daylight when erect, and all his old signs and symptoms.

In many cases that come to me as referee the miner's representative has said, "We all agree that the man has

nystagmus", but the insurance company had taken the man from doctor to doctor until at last one was found to certify that he had not got the disease. Of course, the workman follows the same course until he can get a certificate that he has miners' nystagmus. It is just what the Act is asking for, a referee's report can only be given when there is a conflict of medical evidence. How can a referee assert that a man has not the disease after one examination? He can only say that "to-day he shows no evidence of it."

A reliable opinion can only be given after repeated examinations. My view is that all cases of miners' nystagmus should be dealt with as they are in *The Refractories Industries (Silicosis) Scheme, 1925*, a copy of which can be obtained from H.M. Stationery Office, or through any bookseller.

A joint committee of the employers and workmen (not exceeding four on each side) should be formed in each district to facilitate the working of the scheme. They should have the right of nominating two surgeons, to be appointed by the Secretary of State, to act as a medical board. All newly engaged workmen must be examined by one or more officers of the medical board before the engagement is ratified. The workmen must be examined periodically at the prescribed intervals, and the decision of the medical board be final.

In this way much unnecessary expense and waste of time will be avoided, and the interests of both employers and workmen are guarded.

At present, if a referee signs up a man as able to do light work at bank, in almost every case the employer can give the man no light work, and he is given, say, half the difference between his old wages and those which he is certified as able to earn, and with the unemployment dole he is often able to obtain more money than if he were at work.

Employment suitable for miners' nystagmus cases must be provided, and there should be industrial schools attached to them (as in the army scheme) so that each man can learn the trade which he fancies. This must be subsidized, and where is the money to be obtained?

I feel sure that more than half the money given as "the dole" is given to those who do not deserve it. It has destroyed the morale and independence of the working man, and especially of the young lad, more than anything else. A lad will keep a job for a month or two and then get turned off on purpose to get the dole. The money saved by more stringent investigation as to the urgency of the applicant's claim would be amply sufficient to provide all the funds needed.

In my district it is always the best workman who comes before me with the most advanced evidence of the disease, for he goes on hewing until he can hear no longer. I am convinced that if a man were to apply for examination within the first six weeks of the occurrence of any symptoms he would, on being given other employment, lose them in a few months, and would be quite able to do any other work away from a colliery that he fancied.

In former papers I have shown that some men acquire the disease and others escape it though doing the same work, and that the disease is increasing at an alarming rate. It seems to me that without doubt some are born with a predisposition to the disease, and this predisposition is clearly hereditary, further, that during the year 1922 I found that, in considering over 35,000 underground workers, of whom about one-third were hewers, the percentage of hewers who required the disease during that year was very nearly four times the percentage of non-hewers, hence hewing, or something connected with hewing, was far more important than deficiency of light, to which both classes were equally exposed (*BRITISH MEDICAL JOURNAL*, May 5th, 1925).

From this it follows that the pit villages are hotbeds for cultivating the disease. The only reasonable scheme for eliminating the disorder is to clear out from the pit villages all those who have acquired the disease, with their families, until eventually they are inhabited by only those who are immune.

It is a disgrace to the profession that no steps whatever have been taken or even suggested for wiping out this scourge. I should wish that, if my proposal is adopted, all new cases should apply to the medical board for examination within six weeks of the occurrence of symptoms, and only receive compensation on their signing an undertaking not to engage in any colliery work again. As soon as the workmen realize that they will be attended to and taught new ways of earning their livelihood they will be ready and anxious to do this, instead of being branded as derelicts for life—I am, etc.,

Newcastle-on-Tyne, Sept. 11th.

A. S. PERCIVAL

#### CONVULSIONS DURING ANAESTHESIA

SIR.—Since reading Dr. Pinson's article on this subject May 28th, 1927 (p. 956), and the two letters in the issue of September 10th, I have had a case of this curious phenomenon. The point of interest is that again the ether bomb was used, as in all Dr. Pinson's cases.

The case was one of a strong and healthy man, aged 50, with a perforated appendix. There was no previous history of epilepsy. While stitching up the peritoneum the convulsions began by facial twitching, "catching" breathing, and gradually extended to the arms and hands. The anaesthetic was stopped immediately and under the influence of oxygen the colour returned to normal and the twitching gradually subsided, the labial muscles being the last to become quiet.

There is no doubt in my mind that the convulsions were caused by the concentrated ether and the excess of CO<sub>2</sub> which had accumulated under the numerous coverings of the frame—I am, etc.,

DAVID C. DICKSON, M.B., Ch.B.

Dunfermline, Fife, Sept. 22nd.

#### DEATH CERTIFICATION

SIR.—In your account of Sir George Newman's annual report on the state of the public health there is a statement that I should like to see ventilated.

He compares unfavourably the present system of certification with the practice in Switzerland where the certificate is a confidential document and the friend of a deceased person has no access to the statement of causes of death.

To these words I emphatically subscribe. Particularly do I do so when I recall two cases that I was cognizant of.

The first was that of a man aged 67 to whom I was called for an ulcerated patch on the back of the pharynx. I was puzzled as to the nature of it and called in a leading laryngologist who diagnosed it as Vincent's angina and prescribed accordingly. The ulceration extended and the tongue became involved with patches of ulceration that struck me as possibly syphilitic. I accordingly brought him to see a leading authority on that subject, who at once pronounced it was syphilis pointing out further that he had syphilitic osteitis of the bones of the tibia. No cause of infection could be found at the usual site. The patient died three months after.

Here was a man, well known in his district with sons and daughters, brothers, and cousins all round him, honoured and respected by everyone, who was to be sent to his grave branded as a profligate and immoral man if I wrote on his certificate "primary caudo syphilis." I did not do it, but added "septicaemia," in the hope that the certificate would not be accepted as such by the Registrar General, but that I should bear in a few weeks, which I did, and wrote a full explanation.

The other instance (not under my care) was that of a distinguished man who, at the age of 75 developed tertiary ulceration of the larynx. The certificate was signed as such and I have never forgotten the horror of his widow when she heard the cause of his death.

I am certain that there are few medical men of standing who could not mention similar cases, and I feel that it would save a good deal of unhappiness and would lead to more accurate certificates if these were made confidential—I am, etc.,

Place, Sept. 11th.

H. J. HILDICE, M.D.

## POOR LAW MEDICAL SERVICE

SIR,—I have read with interest the letter of Dr Cyril Thomas on the subject of the Poor Law medical service (September 17th, p 519)

His experience of large mixed institutions has not been particularly fortunate, as there are examples of institutions dealing with large numbers of sick where amicable relations between the master, matron, and medical officer are maintained. The duties of each are clearly laid down in the orders of the Ministry of Health, and if the spirit of these orders is loyally carried out there are few opportunities for serious trouble.

If the chief officials are antipathetic, or if their mutual confidence is destroyed, the situation becomes very difficult. The fault is not invariably on the side of the lay staff.

Alterations in the orders are desirable to fit them for various conditions, but I question if the problem of efficient hospital management will be solved by placing all institutions of the type referred to under medical superintendents, or by appointing a doctor as both master and medical officer. In the meantime, some institutions with mixed administration provide experience for the young doctor not markedly inferior to that in separate infirmaries.—I am, etc.,

HENRY H. MACWILLIAM,  
Medical Officer, Walton Institution, Liverpool

September 21st

SIR,—At the last meeting of the Poor Law Medical Officers' Association it was suggested that I should write to you on the subject of appointments under the Poor Law Institutions Order. The Poor Law Medical Officers' Association has been discussing the matter for some time past, and has made efforts to collect opinions from men in this group—a difficult matter.

There are over 600 unions in England and Wales, and about fifty have separate infirmaries. In over 550, therefore—with a few special exceptions—these institutions are governed by the Order named. Many of the latter contain what are practically general hospitals, some of which have grown to considerable size. Actual conditions and procedure vary in them, although under one Order, and degrees of development vary. Between them—that is, of the 550 odd institutions—they contain a large proportion of the total hospital beds of the country.

There is little liaison between the three main groups of Poor Law doctors, and none at all between members of the group to which I refer specially.—I am, etc.,

Southend-on-Sea, Sept 18th

R A S SUNDERLAND

## FELO-DE-SE

SIR,—In reference to Dr S A Winstanley's most pertinent remarks on *felo-de-se* and your footnote on the same (September 17th, p 518), the essence of this case is, as you point out, Was she pregnant?

Dr Winstanley says "as a matter of fact she was not pregnant." How can he know this as a fact unless there was a *post-mortem* examination? On the other hand, how does the coroner know that as a fact she was pregnant? Unless he did so know he cannot say she was guilty of felony or *felo-de-se*. Was there a *post-mortem* examination?

The mere fact that the woman believed herself pregnant or intended to procure abortion on herself is irrelevant under Section 58 of the Offences against the Person Act of 1861. Moreover, apart from the verdict of *felo-de-se* being wrong if based merely on a presumption of, instead of the fact of, pregnancy, the whole inquest is void on the ground that a coroner sitting without a jury cannot return a verdict of *felo-de-se*. Section 13 (2) Coroners Amendment Act, 1926, amended the Act of 1887 and allowed a coroner to hold an inquest without a jury except when "there is reason to suspect, (a) that the deceased came to his death by murder, manslaughter or infanticide, (b) ... *Jeris on Coroners*, 1927, states "This appears to include self-murder or *felo-de-se* verdicts, as the form of inquisition with jury is given in the schedule to the Statutory Rules,

1927, No 344/L13. So Dr Winstanley or the relatives could appeal to the Lord Chancellor for a fresh inquest on the claim that (1) if pregnancy was not proved the verdict was misadventure and not *felo-de-se*, (2) if pregnancy was proved the *felo-de-se* verdict made a jury obligatory.—I am, etc.,

September 17th

MIDICO-LEOAL

## "HANGED, DRAWN, AND QUARTERED"

SIR,—An experience that occurred to me whilst acting as regimental medical officer during the war may be of interest as bearing on the article in your issue of August 6th (p 230) and the letter published on September 24th (p 569).

In October, 1914, a party of Germans penetrated through our very thinly held lines near Neuve Chapelle. They could not get back and were rounded up. During the scrap one received a bayonet wound in the abdomen. This man walked a hundred yards to my aid post holding the whole of his intestines in his hands. Whilst doing what I could for him he talked continuously. Shock gradually overcame him and he died about six hours later.—I am, etc.,

CARL HYLM, D S O, M C  
Great Horley, Colchester, Sept 25th

## THE TESTING OF DISINFECTANTS

SIR,—In a recent letter from this laboratory concerning the testing of disinfectants (July 9th, p 79) we drew attention to some misstatements in a standard textbook on bacteriology, in regard to a method of testing disinfectants originated by the father of one of us, in collaboration with Mr J T A Walker. We gather that this letter has caused misapprehension in certain quarters, and we wish to state that the purpose of the letter was no more than to point out the inaccuracies in the book under discussion, and there was no intention of suggesting that the method of testing originated by Dr S Rider and Mr J T A Walker had in any way been modified or altered, whilst still maintaining their names. We express regret, and tender our apologies to Mr Walker, for any apparent misstatement or ambiguity in the wording of the letter.—We are, etc.,

ERIC K RIDFAL,  
A SCIENTIST  
Chemical Laboratory, Victoria Street,  
London S W 1, Sept 27th

## Universities and Colleges.

## UNIVERSITY OF LONDON

## UNIVERSITY COLLEGE

The session 1927-28 opens at University College on Monday next, October 3rd. Students of the Faculty of Medical Sciences will be received by the Provost and the Dean on that day as follows: First year students between 10 a.m. and 1 p.m., students of later years between 2.15 p.m. and 4 p.m.

The following awards have been made: Bucknill Scholarship (160 guineas) E A Deynash 1st Medical Exhibition (55 guineas) J Apfelbaum, Second Medical Exhibition (55 guineas) R B Ogborn, *proxime accessit*, M Steinberg.

Public lectures that have been arranged for the first term include the following: The first Riekman Godlee Memorial lecture "Nations," by Viscount Cecil of Chelwood.

By President of the Royal College of Physicians on "Hydrogen ion concentration." Dr Philip M. Huggins, a lecture on "The static reflexes of Maggots: how animals get right way up and keep so," by Professor A J Hall of the University of Sheffield.

Particulars of these and other public lectures may be had on application to the Secretary, University College, London, W C 1. A stamped addressed envelope should be enclosed.

## LONDON HOSPITAL MEDICAL COLLEGE

The following entrance scholarships have been awarded at the London Hospital Medical College: Price Scholarship in Science £50 £100 K H C Hester Second Scholarship in Science £50 A J P Brown Ipsom Scholarship in Science (open to students of Ipsom College—free medical education) W A Hall of University Scholarships (open to students of the University of Oxford and Cambridge) (1) Freedom Research and Scholarship in Pathology, £100 R H Dobbs, (2) Price Scholarship in Anatomy and Physiology, £75, A Lister.

## Obituary

SIR ARTHUR SHIPLEY GBE, SC.D., LL.D., F.R.S.,  
Master of Christ's College, Cambridge

THE death, on September 22nd of the Master of Christ's though primarily a loss to science and to the University of Cambridge is also a loss to medicine because Sir Arthur Shipley was a good friend to generations of Cambridge medical students and in various ways throughout a strenuous public career, showed his practical interest in the work of our profession.

Arthur Everett Shipley was born in 1861 and left University College School in 1879 with the intention of studying in medicine. But after a year at St Bartholomew's Hospital where, with the help of Stephen Pigot, he had dissected the leg of the wife of the butler of the first Napoleon, he went up to Cambridge and (again to use his own words) "fell under the glamour of Morphology." It was about this time that Francis Balfour was finishing his epoch making work on comparative embryology. Another Cambridge professor, but requiring the older school, who influenced Shipley much in his undergraduate days was Alfred Newton, a dull lecturer but a great power in the world of ornithology and an inspiration to receptive minds. Newton's Sunday evenings in the old Lodge at Magdalene saved zoology as the science of living animals in Cambridge. Shipley gained a first in both parts of the Natural Sciences Tripos, became a Fellow of Christ's and demonstrator of comparative anatomy in the University. His own researches (for which he was elected an F.R.S. in 1904) were mainly in the field of invertebrate zoology, but he took a large share in developing the teaching of zoology generally at Cambridge. He wrote much and pleasantly on many subjects and was an admirable editor of scientific journals. He was moreover, a first-rate man of affairs, excellent on committees and such like bodies whether as chairman or ordinary member. In 1910 he was elected Master of Christ's and at once became just what the Head of a House should be in the old days, blending aulous regard for old traditions with liberal ideas and informal courtesy. By none was he better liked or more admired than by the medical students and graduates of his own college and many of them have a repertory of "Shipley sayings" for intimate occasions.

Shipley's period of office as Vice-Chancellor of the University coincided with the most difficult years of the war. Besides taking a close interest in the development of the 1st Eastern General Hospital—that town of huts on the 'Backs'—he made the Master's Lodge from 1915 a convalescent home for wounded officers, at no small sacrifice of his personal comfort. It was typical of him to find time in the enormous days to devise a dinner table plate for the use of soldiers and sailors who had lost an arm and an appliance by which an armless man could turn the pages of a book both were described by him in our columns. Encouraged and guided by the Vice-Chancellor Cambridge threw itself into the war, and the high honour of C.B.E. conferred upon him in 1920 was fitting recognition of indefatigable work for his country, both in public and behind the scenes. Shipley's very entertaining and instructive series of papers "The minor horrors of war" and "More minor horrors" first appeared in the *BRITISH MEDICAL JOURNAL* in 1914 and 1915, and were afterwards reprinted in book form. Another direction in which he served our profession was by membership of the Central Medical War Committee and in its early months he shared the duties of vice-chairman. He was also a Bent Trustee and an elected trustee of the Hunterian Collection. Of his many other distinctions and services this is not the place to speak.

We are indebted to Sir HUMPHRY ROLLESTON Bt., Regius Professor of Physics, for the following appreciation.

Arthur Shipley belonged to the new order of heads of colleges who on distinctions in natural sciences rather than in the old order of mathematics in this capacity he was

pre-eminently successful, for he took a rather lively interest in all, and especially the younger, members of the college, and, knowing them well looked after their present and future in an exceptionally sympathetic and effective manner. His genuine kindness of heart was also shown by the affection he inspired among the servants of the College. He was a connoisseur not only in the art of living but in entertaining others so as to make them feel thoroughly at home in "the Lodge"—which he had made both comfortable and impressive—as was well shown by his unselfishness in giving up the quiet Lodge to wounded officers in the war. In addition to holding with distinction the Vice-Chancellorship of the University during a critical time in the war he was a power in the outside world, much in request on committees, and thus brought influential personalities into touch with Cambridge. Keenly interested in many directions, especially in the application of biology to practical problems, such as the use of agriculture, he travelled much in connexion with his activities. Last spring he returned from such a visit to the West Indies ill and depressed with prophetic forebodings about his health, and it is sad that he has so soon followed his lifelong friend the late J. G. Adams, Vice-Chancellor of Liverpool, upon whose memoir he was engaged until almost the end. He wrote much and always in an easy and attractive style, ever a popular after-dinner speaker. He had at his command a fund of good stories which he told in an inimitable manner with great effect. It is certain that with his mine of curious information he could have written a fascinating account of Cambridge life and manners during the last forty years and indeed this would be an appropriate addendum to "J" (A Memoir of J. W. Clark 1833-1910) which he brought out in 1913. His death leaves a gap which many will long feel can never be so exactly filled.

ADRIAN STOKES DSO, OBE, M.D. DUBL.,  
F.P.C.I. M.P.C.I. Lond.

Sir William Dunn Prof. of Pathology at Guy's Hospital  
London University

THE death of Adrian Stokes at the early age of 40 robs the Empire of one of the most brilliant students of medicine of this generation and of a man with many wonderful and lovable qualities. He was born at Lausanne on February 9th, 1887. His father was the late Henry John Stokes, I.C.S., of Howth, co. Dublin. His great grandfather, William Stokes, was regius professor of medicine in the University of Dublin from 1830 to 1843 and his grandfather was the great clinician William Stokes. It is interesting to recall that in 1826 William Stokes nearly lost his life from typhus, which he contracted whilst working among the sufferers in the great Dublin epidemic.

Adrian Stokes was educated at St. Stephen's Green School, Dublin, and in 1905 entered Trinity College with which his family had been associated for many generations as Fellows, scholars and graduates. Here, and at the Meath Hospital where his grandfather had been a physician and his uncle, Sir William Stokes a surgeon, he studied medicine with distinction obtaining first-class honours a senior moderatorship and the Banks prize. While still a student he published an excellent paper on a "Rare abnormality of the heart and great vessels." He graduated M.B., B.Ch. in 1910 and proceeded M.D. in 1911, and acted for a time as demonstrator in anatomy. He obtained the diplomas F.P.C.I. in 1912 and M.R.C.P. Lond. in 1924. In 1912 he was elected to the medical travelling prize, but with characteristic generosity resigned it in favour of the 'proxime accedens.' The prize being again awarded to him the following year he went to the Rockefeller Institute in New York, where he engaged in research for eight months.

He returned to Dublin as a assistant to the late Dr. O'Sullivan, professor of pathology at Trinity College, where he continued to work till the outbreak of war. He immediately volunteered for service, and shortly afterwards went out to France with a medical unit from Dublin. He took with him his own motor bicycle and sidecar, which he packed with laboratory apparatus, thus being

<sup>1</sup> Life of Alfred Newton, B.A., F.R.S., vol. II, Chap. VII, p. 100.

the actual parent of the mobile laboratories which were to play such an important part in the army medical services during the latter part of the war. Shortly afterwards a friend had a motor caravan equipped as a small pathological laboratory for him, thus became No. 1 Mobile Laboratory, and remained with Stokes until he was demobilized in 1919.

In 1915 an outbreak of enteric fever amongst the civil population of Belgium Flanders aroused anxiety, and Stokes was detailed to cope with it. It was mainly due to the hygienic measures he took that the disease never spread to the large number of British troops billeted in the affected area. He published an account of his work in the *Lancet* under the title of "Examination of enteric convalescents." For his services in this connexion he was appointed Chevalier de l'Ordre de la Couronne by the King of the Belgians. By discovering the carrier, he was also the means of arresting a typhoid epidemic in the Guards Brigade in 1915. During most of his service in France he was attached to No. 10 Casualty Clearing Station at Remy Siding, near Popeinghe, but his influence was felt throughout the war area. Though he never neglected his official duties as pathologist, he was always ready to help in any capacity. In September, 1914, he rode 140 miles to fetch a supply of urgently needed tetanus antitoxin, and in times of stress he would act as anaesthetist or surgeon.

In the spring of 1916 an epidemic of jaundice broke out among the British and French troops in France and Flanders. Stokes was prominent among the small group of British officers whose investigations proved that the disease was caused by infection of the liver and kidneys with the same spirochaete which Inada and his fellow workers had discovered in 1914 in the blood and urine of the epidemic jaundice prevalent among Japanese miners. He found the spirochaete in rats caught in trenches in which the disease had occurred, and by showing that the infection was spread by the presence of their urine in badly drained trenches he was able to indicate how the epidemic could be stamped out. He proved that the jaundice was caused by the inflammatory changes in the liver, which produced obstruction of the smallest bile ducts, and that haemorrhagic nephritis at the same time gave rise to haematuria. He with J. A. Ryle published joint papers on the subject in the *BRITISH MEDICAL JOURNAL* in 1916, and in the *Lancet* the following year. He did work of great value in connexion with all the other infective diseases which occurred in the army. He took an active part in examining contacts with cerebrospinal fever cases, and made himself responsible for teaching the medical officers of the units of his neighbourhood the methods of diagnosis and of treatment with appropriate serum.

Stokes did much to improve the methods of preventing and treating the severe forms of wound infection, and was the first in France to isolate the organism of gas gangrene in the blood stream. When a crowd of victims of severe phosgene gas poisoning arrived at his casualty clearing station he found that the old-fashioned mask was still being employed for administering oxygen. Since it was proving both wasteful and ineffective he collected all the available rubber catheters and tubing in order that a satisfactory flow of oxygen could be given through the nose, with the result that innumerable lives were saved which would otherwise have been lost. The method he then introduced has now been widely adopted in civil practice. All who came into contact with him agree that no man did more to improve the lot of the sick and wounded than this young Irish officer, who was only 27 at the outbreak of war. He was directly responsible for the saving of countless lives.

After the armistice he served in Cologne, where he did most valuable work in helping to restrict the ravages of venereal disease. He was several times mentioned in dispatches and was awarded the D.S.O. and O.B.E. for his services with the army.

In 1919 he returned to Trinity College, Dublin, as professor of bacteriology and preventive medicine and pathologist to the Royal City of Dublin and Adelaide Hospitals.

In 1920 he was asked to go to Lagos, West Africa, with the Rockefeller Yellow Fever Commission, his investigations on epidemic jaundice in France having attracted the attention of the authorities. He accepted readily, as it was a form of work that specially appealed to him. He spent about six months on the coast, but as he only saw one case—a man who escaped into the bush to avoid examination—he had no opportunity of carrying on any investigations.

In October, 1922 Stokes was appointed Sir William Dunn professor of pathology in London University at Guy's Hospital. At that time interest in pathology among the students was at a low ebb. Naturally attracted by the living interest of clinical work, they regarded any course as sufficient for non-attendance in the department. The course then covered a period of three months, but Stokes from the first insisted that it was impossible for pathology to be taught in less than double that time. The suggestion met with considerable opposition, and it was largely due to the charm of his personality that he eventually had his way, a whole winter session being now devoted to the subject. In order to give the students every opportunity to attend he duplicated the practical classes, although this could only be done at the sacrifice of his own time. When he first came to Guy's he threw himself into the task of perfecting his knowledge of the branches of pathology with which, as a bacteriologist, he had previously been comparatively unfamiliar. Few knew what an amount of reading and study this entailed, but all appreciated the success which followed in the vast store of accurate knowledge he accumulated. The students were quick to appreciate his willingness to help them, and they soon found that his department was free from any trace of red tape. As a result the attendance at the pathology classes improved in an extraordinary way. Wherever previously the pathologists had complained that the clinicians prevented the students from giving them a fair share of their time, the complaints now came from the clinicians, who found themselves deserted by their clerks and dressers when pathology classes were being held. He arranged a weekly demonstration on fresh *post-mortem* material, which was always well attended and was of the greatest practical value. With him the interests of the students always came first, and he fought for his subject because he believed that a knowledge of pathology was essential in the make-up of a "good doctor." It was his custom to offer a prize, at the conclusion of each course, on the results of a special examination.

During his four years at Guy's Stokes made a unique position for himself. Members of the staff, house officer and students constantly sought his advice and help in the manifold difficulties they encountered in the wards, and they rarely failed to profit from his wide knowledge of the literature, great experience, and unbounded common sense. He realized from the first that a hospital pathologist should not live solely in his laboratory, but should be a regular visitor to the wards. In addition, once a week he made a round with some of his medical colleagues, joining in the discussions on difficult cases. His department was thus not merely a scientific institute, but formed a valuable unit in the everyday work of treating the sick pool of the hospital. He took a keen personal interest in any student who showed a desire to learn, and especially in those who wished to tackle a problem of their own, for he was never too busy to help or advise.

Many valuable contributions to scientific literature, generally published in the hospital *Reports*, came from his laboratory at Guy's. Without exception, however, they appeared under the names of others, the majority being students or recently qualified men, who performed investigations suggested by him and under his direction. In spite of their protests he always deleted their acknowledgments of his encouragement and help from the manuscript. Perhaps the most important investigation of this kind was that of achalasia of the cardia (so-called cardiospasm) by one of his most promising students. In every one of the eight specimens examined inflammation or degeneration was found in Auerbach's plexus in the neighbourhood of the sphincter, thus explaining its failure to relax on the arrival of a peristaltic wave during deglutition. On

investigations dealt with the infective gastritis associated with the achlorhydria of subacute combined degeneration of the cord, neutro suppurative gastritis, diffuse polyposis of the stomach, and aleukemic leukaemia.

In the spring of 1927 the Rockefeller Commission on yellow fever in West Africa again sought Stokes's assistance. Their investigation had led to no definite result and it was hoped that his clear judgement and genius for research would make it possible to unravel some of the difficult problems with which the Commission was faced. It has long been known that yellow fever, as it occurs in South America is propagated by the common domestic mosquito, *Stegomyia fasciata*, and recently Noguchi described a *Leptospira* which he believed was the cause of the disease. As the epidemiology of the yellow fever of West Africa is very different from that of South America, doubts have been raised whether the disease in the two continents was really identical. It was therefore necessary to discover whether the clinical and pathological characters of the West African disease were identical with the better known South American disease, and whether the fever was like the latter transmitted by mosquitoes. This was just the kind of problem which fascinated a man of Stokes's character, and his only doubt as to whether he should accept the invitation of the Rockefeller trustees came from his dislike of neglecting his duties at Gur's for six months, for no man ever interpreted duty more strictly or adhered to it more conscientiously. Reassured on this point he accepted the invitation and proceeded to Lagos in June. His first letter home was written from Accra a week after his arrival on the coast.\*

We bought three chumps at Freetown one tame and two recently captured. We landed here instead of going on to Lagos as there was a nice actual epidemic going on in a village about thirty-five miles away. I brought off two here and sent one on to Lagos the big wild one I need hardly say and we have attempted to infect both from three cases of yellow fever each. Neither shows any sign of doing anything. One of them is very ill with cancerum ovarii and I think will die from it but it has been for two days more it will be ten since we inoculated him and pretty certainly not a take for yellow fever. If the chump don't take we have very little to fall back on. We had two good post-mortem examinations on genuine cases with typical liver and kidneys but there seem to be fewer cases the last few days. It is very hard to diagnose and is apparently a trivial disease until you die. The natives are hardly ill at all and the jaundice is often quite unconvincing.

A fortnight later he wrote

We have infected some Indian monkeys five out of six inoculated with blood from yellow fever cases have died with a good pathology. We have failed to pass the strain to others this suggests an intermediate life history. I think it is a winner. No *Leptospira* at all found.

On July 7th he wrote from Accra

I came back here from Lagos about ten days ago as there was another outbreak on the Togoland frontier. Two early cases were tried on monkeys. One died during the incubation period and the other ran a typical fever for four days and then recovered.

On August 15th he wrote from Accra

The hunt is going all right at Lagos and I am going back on Monday. They were able to run the strain through three monkeys and then alas! had no more and we had to depend on mosquitoes to keep it till more came from home and they did

It should be noted that the following extracts are from private letters and must not be regarded as accurate reports of the investigations referred to.

the job all right so far as I can see from records they have sent me.

This proves our case fairly well and as we can get no *Leptospira* at all it seems that organism is the cause of yellow fever. The last news I had which was a cable seems to imply that we have for the first time transmitted one of four tried and that seems good enough to chance a fourpence on. The third monkey had a beautiful clinical history and jaundice and albuminuria and all the right things at the post-mortem examination and he of all showed a liver lesion that was almost typical of yellow fever with quite obvious and zonal necrosis as well as the fatty change. We still have the difficulty of not having a white man to monkey transmission and no post-mortem examination on a case that has been used to infect a monkey. That will be a question of time and fortune but I am quite confident it will be all right.

I am going up country to-morrow to get some convalescent serum from a recovered European case to do protection experiments with when I get back to Lagos. We went when he got ill and I tried a monkey but it was three and a half days after the illness started and nothing happened. One must get it in forty-eight hours to get a winner so far as we know at present. However, protections are good evidence.

His last letter was dated August 26th

'We are a bit full of ourselves as we have the fish hooked all right right down in the belly and unless we are careful and break the tackle it will only be a question of time. The time may be years but it must come. He rose to a grey monkey in May and we hooked him for early in July and now we can transfer it by blood or mosquitoes at will and can protect the animals by convalescent serum and so on. Of course the gaffing of the bug will be the thing that takes time but getting a susceptible animal is a first and essential step. We have about 90 per cent of successful transfers with blood and about the same with mosquito and we have had about a dozen animals die so we think it is very nearly certain. The pathology and clinical picture is good on the whole. What we want is another strain or two isolated from human cases and best of all a strain isolated from a patient that comes from autopsy.'

I have again ventured in cutting mosquitoes and it is interesting to know that one has the virus under one's eye and cannot see it. I am cutting them in series—a normal one fed five days and two fed twenty-six and forty-two days. You get them all parallel and cut them from before backwards in series and then gaze in rapid admiration at nothing at all to see. They have lovely eyes though and

(Elliott and Fry, London)

ADELIN STOKES

lots of other nice things to distract you.

From the meagre details available it seems probable that Stokes contracted yellow fever from the bite of an experimentally infected mosquito. He became suddenly ill on September 15th, about five weeks before he was due to sail for home. He was removed to the European Hospital on the following morning. He died on the evening of the 19th. He was buried next day at the Ilorin Cemetery after a service conducted at the Colonial Church by the Bishop of Lagos.

As a sportsman he showed just the same delightful and infectious enthusiasm that he did in his work. He was in the Trinity College XI and played hockey, lawn tennis, and squash racquets well. But the sports he enjoyed most were sailing, fishing, and shooting. His summer holiday was nearly always spent in Ireland, and he had to leave on his return to tell about his experience with the trout and salmon. During September, until the commencement of the autumn term claimed all his time, one day a week was regularly given up to shooting. It was typical of the man that on these occasions, though an excellent shot, he would always endeavour to place himself where the birds were likely to be fewest and where the walking would be most arduous. He was extraordinarily popular, everybody liked him. An impulsive, warm-hearted Irishman, he was generous to a fault, and his boundless sympathy with those

in trouble allowed him no rest until he had done everything possible to put things right. His flat at Morda Vale was a refuge for the sick in body and in spirit, he would give up his own room and, single-handed, would nurse his guest back to physical and mental health. A superficially gruff manner hid a heart of gold, and the less to the many who were privileged to be his friends is irreplaceable.

Dr T. GILMAN MOORHEAD, Regius Professor of Physics, University of Dublin, in the course of a warm tribute, writes

Adrian Stokes, one of the most brilliant of Irish students of medicine in this generation, entered the Medical School of Trinity College in 1905, he devoted himself at once with intense energy and enthusiasm to his medical studies, but also found time to take part in other activities of university life. He was a fine cricketer and an all-round sportsman, but a somewhat negligent student of Arts. For some years he acted as secretary of the Dublin University Biological Association, and was a prominent figure in directing the energies of that association in his student and also in later years. Although eminently adapted for clinical work, and especially for surgery, his real bent from the beginning was for the laboratory. He early showed a flair for research, and in his student days published in the *Journal of Anatomy* a remarkable paper on a rare malformation of the heart. Coming under the influence of the late Professor O'Sullivan, he took up the study of bacteriology, and threw all his abounding energy into this branch. As an undergraduate, almost from the moment of his entering the medical school, he became a marked man, not merely for his brilliant intellectual attainments, but also for his strength of character and his capacity as a leader of men. It was recognized by all his teachers that the genius of his great predecessor William Stokes had been reborn in him. On his return from working in the Rockefeller Institute, New York, he accepted the post of assistant in the Pathological Laboratory, Trinity College, and at the same time, with the object of bringing closer together clinical and pathological aspects of medicine, he undertook for a short period the work of an assistant physician at the Royal City of Dublin Hospital. Throughout the remainder of his life this object retained his deepest interest. He felt that clinical and laboratory work were to some extent estranged, and he never ceased in deeds and in conversation to endeavour to bring pathologists and clinicians more closely together. In the before-mentioned positions his powers as an original thinker and investigator became at once apparent, and many who came in contact with him felt that he had introduced a new stimulus into the medical life of Dublin.

At the end of the war he returned to Dublin, and for a time was professor of bacteriology in the University. During his tenure of this post he continued his scientific work, and published several papers of outstanding merit, including one with Professor Biggs on an outbreak of dysentery in the Dublin area, and one in conjunction with Professor Wigham on the sigmoid reaction. But, what was even more important, he gained a hold over the minds and thoughts of the younger generation of students, and stimulated many of them to undertake fruitful lines of research. Although he only held the appointment for a few years, his influence is still felt in the direction indicated. A hater of shams, he was satisfied by nothing less than the most rigorous proof. Careless or slipshod work was anathema to him, and no trouble was too great to ensure accuracy. His intense intellectual honesty was always apparent and nowhere more than in connection with his own particular line.

Apart from his reputation and standing as a man of science Adrian Stokes had many friends, and no man better deserved his friends or did more for them. In periods of distress he was always helpful in advice, and never spared either time or trouble to aid those who were in need. Though generous to a fault in expression of sentiment or emotion was foreign to his nature. Outspoken in criticism, he made some enemies, but no one ever accused him of unfairness in controversy or believed his criticism to be personal. There is pathos in a life cut

off with the promise of such rich fruit, had he been granted the normal span of human life he would undoubtedly have further enriched our scientific knowledge of medicine, and would probably have added new pages to medical history. Though he must be numbered among the inheritors of but half-fulfilled renown, he will be remembered as a pioneer who, like others, risked his life joyously and gave it nobly for the sake of scientific truth.

Dr CHARLES EDWARD PAGET, who died on September 11th at the age of 68, was the second of four sons of the late Sir George Paget, K C B, Regius Professor of Physics at Cambridge, and nephew of Sir James Paget, Bt, the famous surgeon. Charles Paget went from Charterhouse to St Bartholomew's Hospital, and obtained the diplomas M R C S Eng in 1882, the L R C P Lond in 1883, and the Diploma of Public Health of the English Conjoint Board in 1889. He acted for some time as private secretary to Sir James Paget, and in 1883 was appointed medical officer in charge of the Westmorland combined sanitary district. Six years later he became medical officer of the borough of Salford, and in 1897 he was appointed medical officer of health for Northamptonshire, which post he held until March, 1926. He was a Fellow of the Society of Medical Officers of Health, and president of its North Western Branch in 1893. For some years he acted as lecturer and examiner in public health at the University of Manchester. His literary contributions included a pamphlet entitled *Healthy Schools*, the handbook of the International Health Exhibition in 1884, and *The Arrangement and Construction of School Sanatoria*, he also collected and edited some of the lectures of Sir George Paget, supplying a memoir of his father. Dr Paget was for many years a member of the British Medical Association, and in 1895 was secretary of the Section of Public Medicine at the Annual Meeting, in the following year he was vice-president of that Section, and in 1910 he was vice-president of the Section of State Medicine. He leaves a widow but no children, his only son having been killed in the war.

Dr RALPH A. R. LANKESTER, who died with tragic suddenness on September 19th while on holiday at Eastbourne, received his medical education at University College, London, and at Durham University, where he graduated M B, B S in 1898. In the same year he obtained the diplomas M R C S, L R C P, and two years later graduated M D. He went to Bradford in 1899 as house-physician at the Royal Infirmary, and eighteen months later joined Dr Messer in one of the long-established practices in the city. In this practice he remained, and was at the time of his death the senior of three partners. Dr Lankester was appointed visiting anaesthetist to the Infirmary when this post was first created twenty years ago, and he was associated with the late Mr Basil Hall (President of the British Medical Association in 1924) during the whole of the latter's term as surgeon. When Mr Hall's twenty years came to an end Dr Lankester retired simultaneously, and was appointed honorary consulting anaesthetist. A colleague writes Dr Lankester was a glutton for work, and in addition to his large private practice was always prepared to deputize at the Infirmary for another anaesthetist. His services were sought on all the important medical committees in the city, he never pushed himself forward, and was as modest as he was unambitious. But his broad common sense, integrity, impartiality, friendliness, and generosity led to his being elected to the British Medical Association Executive, the local Advisory Medical Committee, the Panel Committee, and the council of the Medico-Chirurgical Society. He was president-elect of the latter society. His death comes with a greater shock to his numerous friends because he had never had a grave illness, was a man who did not look his years, and who appeared to be able to take all he had to do "in the day's work," without any show of over-effort or tiredness. He leaves a widow and young son to mourn his loss.

## Medical News.

At the meeting of the Society for the Study of Inebriety, to be held in the rooms of the Medical Society of London, 11 Chandos Street, Cavendish Square, on Tuesday, October 12th, at 4 p.m., Professor W. E. Dixon, M.A., M.D., F.R.S., will deliver the twelfth Norman Kerr Memorial Lecture, on "The tobacco habit."

**VI COUNT CANT.** Lord Chancellor of England, will open the New Reception Hospital in connexion with St. Andrew's Hospital for Mental Diseases, Northampton, on October 14th at 3 p.m. This building will be devoted to the treatment of early cases of mental disorder and can accommodate sixteen patients of each sex. The new hospital is fully equipped with an operating theatre, laboratories, consulting rooms for psychotherapy, and special arrangements for hydrotherapy and electrical treatment.

**AN** Imperial Social Hygiene Congress organized by the British Social Hygiene Council (Carteret House, Carteret Street, S.W. 1) will be held at the Caxton Hall, Westminster, from October 3rd to 7th, under the presidency of the Right Hon. Major General Seely. The subjects to be dealt with include venereal disease in the Army and Air Force, welfare work among seamen, the medical, educational and administrative aspect of social hygiene, the modern treatment of syphilis, the social problems of India, the Dominions Protectorates and mandated territories, the scientific foundation of character training, and congenital syphilis in school children.

The fifth session of the Liverpool Psychological Society will commence on October 4th when the president, Dr. Barton Hill, will deliver his inaugural address at the university on "Dreams and dreaming." This will be followed by a series of papers dealing with various scientific aspects of the subject. Inquiries may be addressed to the secretary of the society, the University, Liverpool.

A course of post-graduate lectures on infant care will be given at the Infants Hospital, Vincent Square, Westminster, on Mondays from October 10th to December 12th at 6.30 p.m. These lectures are intended for health visitors, nurses, midwives, and superintendents of infant welfare centres. The fee for the course is 7s. 6d. A syllabus can be obtained from the secretary, National Association for the Prevention of Infant Mortality, 117 Piccadilly, W. 1.

A PUBLIC conference on the subject of family allowances has been arranged, to be held at the London School of Economics, Houghton Street, W.C.2, on the evening of Friday, October 14th, and the afternoon and evening of Saturday, October 15th. Addresses will be given by Sir William Beveridge, Dr. R. A. Fisher, Professor A. H. Mottram, and others.

THE Fellowship of Medicine announces that from October 3rd to 15th there will be a whole day cardiology course at the National Hospital for Diseases of the Heart; the number is strictly limited to twenty. The Central London Throat, Nose and Ear Hospital holds its usual October courses from October 3rd to 22nd. The central part occupying almost the whole of each day may be taken alone if desired; there will also be strictly limited courses in operative surgery from 10 to 11.30 daily in practical peroral endoscopy and in pathology and bacteriology suitable for D.L.O. students. On October 4th the London School of Hygiene and Tropical Medicine will start a series of bi-weekly clinical demonstrations on Tuesdays and Thursdays at 2 p.m., continuing until October 28th. Professor A. Forster McIlroy will give a series of demonstrations in ante-natal diagnosis and treatment at the Royal Free Hospital from October 7th to 28th inclusive on Fridays at 5 p.m. Later October arrangements include courses in diseases of children at the Paddington Green and Victoria Hospital for children (October 17th to 29th) in gynaecology at the Chelsea Hospital (October 17th to 28th) in electro-therapy at the Royal Free Hospital (October 12th to November 2nd) and in ophthalmology at the Royal Eye Hospital (October 24th to November 5th). On October 3rd a two months course in neurology will commence at the National Hospital, Queen Square. November arrangements include two practitioners' courses in medicine, surgery, and the specialties in the late afternoon courses will be held in diseases of children, diseases of the chest, neurology (West End Hospital), proctology, gynaecology, and in venereal diseases. Commencing on October 17th a series of lectures arranged by the Fellowship and entitled "Practical hints on medicine, surgery, and the allied specialties" will be held on Mondays at 5 p.m. at the Lecture Room of the Medical Society, Chandos Street, W. 1. In the same week a series of clinical demonstrations will open, these and the lectures are free to medical practitioners. Copies of syllabuses are obtainable from the secretary, 1, Wimpole Street, W. 1.

THE Governor of Northern Ireland has appointed Dr. M. J. Nolan, resident medical superintendent of Down County Mental Hospital, to the Commission of the Peace for County Down.

THE Lord Mayor will preside over a meeting at the Mansion House, London, on October 13th at 3.30 p.m., in support of the Central Council for District Nursing, in London. The speakers will include Sir H. Langley Wood, M.P., and Sir William Collins, M.D.

THE Executive Committee of the Invalid Children's Aid Association has issued invitations to a garden party on the occasion of the opening by Lady Leonard of the Hospital and Home for Heart Cases (to be known as 'Heartscase') at West Wickham, Kent, on Thursday next, October 6th, at 3 o'clock.

DR. G. B. HILLMAN, M.B.E., in response to the invitation of the three parties in the City Council has accepted the mayoralty of Watfield for the coming year.

THE honorary freedom of the borough of Oswestry was conferred on September 22nd upon Dr. Robert de la Poer Beresford, the retiring medical officer of health in recognition of his fifty-nine years of service to the borough of which he was mayor in 1909 and 1910.

The Board of Management of St. Mary's Hospital have extended the term of office of Dr. Graham Fittie, M.P., as physician in charge of the dermatological department for a further period of five years as from October 25th, 1927.

A CONGRESS under the name of *Jornadas Medicas de Madrid*, on the model of those recently held in Paris, Brussels, Toulouse, Montpellier, and Marseilles will take place in Madrid from October 18th to 23rd with Professor Sebastian Peces de la Cruz, dean of the faculty of medicine as president, and Professors Gustavo Pittaluga and Dr. Jose Codina as vice-presidents. Further information can be obtained from the general secretary, Dr. Coea, Apartado de Correos, 1220, Madrid.

THE thirty-fourth Congress of the Italian Society of Surgery will be held from October 18th to 21st at Parma, where the sixth congress of the Italian Society of Urology will also be held on October 21st and 22nd.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C. 1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C. 1**, on receipt of proof.

All communication with reference to **ADVERTISEMENTS** as well as orders for copies of the **JOURNAL** should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the **British Medical Association** and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 962 9 63**, and 962 963 (internal exchange four lines).

The **TELEGRAPHIC ADDRESSES** are

**EDITOR** of the **BRITISH MEDICAL JOURNAL** *Antiology* **Westcent London**

**FINANCIAL SECRETARY AND BUSINESS MANAGER**

(Advertisements etc.) *Articulate* **Westcent London**

**MEDICAL SECRETARY** *Medicerr* **Westcent London**

The address of the **British Medical Association** is 16 South Frederick Street, Dublin (telegrams: *Bacillus Dublin*) telephone 4757 (Dublin) and of the **Scottish Office** 6 Drumheugh Gardens, Edinburgh (telegrams: *Associate Edinburgh*) telephone 21351 (Edinburgh).

## QUERIES AND ANSWERS

### INTRAVENOUS MALARIA

MAJOR P. A. J. C. writes to inquire whether the treatment of malaria has been used intravenously and if so for what purpose and with what success.

A. C. E. writes: What is the objection to the routine treatment of malaria by quinine administered intravenously provided all due precautions are taken? On the face of it the introduction of quinine direct into the blood stream would appear to have great advantages over oral administration. I have frequently treated the cerebral type of malaria with intravenous quinine but I have only had experience of two cases of ordinary malaria treated by the intravenous route with immediate success and no relapse.

## TREATMENT OF FLATULENCE

"WRST COUNTRY" ask - - - "I treat recurrent attacks of gastric and a man aged 77, who is suffering from but is otherwise fairly healthy for his age. All the recognized carminatives have, he thinks been tried without success. Cardine tonics, such as digitalis and strychnine, appear to give no relief.

## BORING THE LOBULE

MR PAUL BERNARD LOTH, F.R.C.S. (London, W.), referring to the inquiry of "K W" (September 24th, page 573), writes: The best way to pierce the lobule with the minimum amount of pain is to grasp it in a pair of forceps and then thrust through the centre of the grasped portion a small trocar and cannula as suggested. The end of a gold "sleeper" is inserted in the cannula, and as the latter is withdrawn the sleeper enters in its place. The forceps holds the lobule absolutely steady, makes certain that the hole will be made in exactly the same spot in both ears, and prevents any bleeding.

## INCOME TAX

## Succession to Partnership

"H Y M" asks for advice in the following circumstances: A and B were in partnership for the four years 1921 to 1924. A then took over the whole practice, moving to the place where B had been residing. For 1925 he was assessed at £750, as for the profits of a new practice, but a new inspector of taxes now states that that was wrong and that A should have been assessed on one third of (£1,500 + £1,500 + £750 =) £3,750—that is, £1,250.

"\* \* Strictly the inspector is right in saying that the assessment should have been made on the three years' average basis, seeing that A undoubtedly succeeded to the practice, but if such an assessment had been made A could have applied under Rule 11, Cases I and II, Schedule D, for an adjustment of that assessment to the amount of the profits of the year 1925, so that the final result would have been the same. "H Y M" might put that point to the inspector, presumably he will not desire to press the matter further if "H Y M" has, in fact, discharged his time liability to tax.

## Car Replacement

"C H D R" bought a car in 1923 for £250 and has now sold it for £75, buying a superior car for £400, the price of a car similar to the original one would have been £225. What can he claim?

"\* \* Strictly, only the actual cost of replacement is allowable—that is, the net cost of obtaining a similar car, £225—£75=£150, it is just possible that the local inspector might take the more lenient view that £250—£75=£175 could be allowed. (Our correspondent holds a public appointment, and we are assuming that he does not receive a car allowance from the local authority.)

## Motor Car Allowance

"J P B" replaced his car in 1922 at a net cost of £414—£100=£314, the next replacement occurred in 1925, the cost being £270—£75=£195, and the most recent in 1927 cost (£425—£75=£350). The two earlier replacements were allowed for at the amount of the net cost. What should he claim for the 1927-28 assessment?

"\* \* The inspector of taxes takes the view that if depreciation is allowed on the full value of the car—that is, on £425—then the amount received for the car, namely, £75, should be added to the professional profits. We do not agree with that view. Presumably the car bought in 1925 had, when replaced, become by wear and tear and age unsuitable for the purpose for which it was employed—in other words, it had become obsolete so far as "J P B" was concerned. In that case the allowance fairly came under Rule 7, Schedule D, Cases I and II, as incurred in replacing the obsolete car. Whether given on the ground of "obsolescence" or "renewal expenditure" the allowance had reference to and was measured by the car displaced, and left "J P B" in the position of having incurred a total net capital expenditure of £414, that is the amount on which depreciation is due, and we can find no justification for adding £75 to the profits.

## LETTERS, NOTES, ETC

## PREVENTION OF GOITRE

SIR JAMES BARR (London, S.W.) writes: By chance I happened to notice the letter of "S O" on the above subject in your issue of September 24th. He says "It would be interesting to know if Sir James Barr still uses concussion of the spinous process of the sixth cervical vertebra in the treatment of thyroid enlargement." Concussion of the sixth and seventh cervical spines followed by concussion of the second dorsal spine, is invaluable in all cases of hyperthyroidism and in these cases you should substitute calcium for iodine. In all cases of fibroplastic goitre you should stimulate the function of the thyroid by a liberal use of iodine and concussion of the third and fourth dorsal spines, followed by concussion of the second dorsal spine—which I have termed the fixation complement. From the diet omit milk, cheese, hard water, and all preparations of calcium. As a plexi-

meter I use a conical cork with a diameter of 1 1/2 in at the broad end and about 7/8 in at the narrow end. The broad end covers the sixth and seventh cervical spines and the third and fourth dorsal, while the narrow end should be used on the second dorsal. For a plexor I devised many years ago a small mallet with a handle 7 in long, the whole weighing about 1 lb. There are a good many handsets of these floating about and they can be had for about 6d each from Mr. Winsor, chemist, Park Lane, Liverpool. I always bought them by the half gross, and made a present of a cork and mallet to the patient, and taught some relative how to carry out the concussion, which should be done two or three times daily.

## LOCAL RESISTANCE OF THE CORNEA TO IMMUNIZATION

DR MERR CORLIANS (Hendon), referring to the report by Drs. Dard and Villard of a case of accidental inoculation of the eye of a man with vaccine lymph (See *Epidemiology*, August 27th, para 189), draws attention to his own investigation of vaccine variolae, published in the *Journal of Tropical Medicine and Hygiene* April 15th and May 1st 1926. He remarks that the experiences recorded by these French observers confirm the experimental results which he obtained in the rabbit. He concluded that the phenomenon demonstrated in previously immunized rabbits of retreating sensitiveness of the corneal epithelium to vaccine inoculation while the skin remained refractory might possibly indicate the presence of a negative phase in the rabbit and the want of protection against variola in this animal.

## "SUBINVOLUTION PERITONITIS" (?)

MR T S M CONNELL, F.R.C.S. Ed. (Birmingham) writes: Dr Douglas A. Mitchell of Bath has advisedly called attention to the condition which he queries as "subinvolution peritonitis" (*Journal*, September 24th, p. 574), and he is to be complimented on his description of the physical signs. I have met several similar cases, and after careful examination and consultation with surgical colleagues in every case we have been compelled to open the abdomen on the probability of finding an appendicitis before establishing the diagnosis. While there is present a general soft, tender infiltration of the pelvic cellular tissue making it difficult to gauge exactly the size of the uterus with some irregular bleeding, the symptoms are so similar to an acute attack of appendicitis following on several slight attacks, that it is nearly impossible to avoid this diagnosis. This is explained by the involvement of the small intestinal coils. The omentum seems to take little part in confining the inflammation. I think the clue to the condition is to be found in the history of a recent confinement or abortion. Dr Mitchell apparently considers that four months is too long for an infection to be dominant, and also that an apparently straightforward confinement precludes the probability of consequent infection. My experience is that both these ideas are erroneous. It is not an extreme rarity to have a patient admitted to my care with pelvic infection usually of the fibrinolytic type, several weeks after an apparently normal confinement. I have only once been able to isolate the organism in the cases in question, and then it was a diplo streptococcus. I hope that I may be able to diagnose the next case correctly by keeping these points in mind since the usual fatal of gynaecological treatment, Fowler's position, an enema, vaginal douching, and hot applications to the lower abdomen, suffices for a cure.

## PREGNANCY AND GLYCOSURIA

DR D M MACDONALD (Ainslie, Westmorland) writes: The correspondence under the above title reminds me of a remark made to me many years ago in a ward in the Royal Infirmary, Edinburgh, by the late Dr James. He was discussing this question in relation to a patient at that time under his observation, and stated that when sugar occurred in pregnancy the subsequent birth was invariably a female. In my experience this has always been so. It would be interesting to know if other practitioners find the rule constant or subject to exceptions.

DR J BARRIE SMITH (London, S.E.) writes: The sugar can be easily differentiated by my simple method described in the *BRITISH MEDICAL JOURNAL* some months ago for alcohol. The apparatus consists of a small phial half an ounce, and a stem thermometer fitting into the preferably long and stoppered phial. The oxidizing fluid is a saturated solution of potassium permanganate 4 c.c.m. with dilute sulphuric acid 2 c.c.m. The graph, vertical temperatures, and horizontal minute observations made from the differences of oxidation of the sugars, indicate quantity and sort, 2 c.c.m. of the solutions or of the urine is sufficient. Oxidizer and oxidizable should be at the same temperature at the start. Sugar of milk and cane sugar may take twenty minutes for their maximum, glucose, eloh, minutes, maltose approximating glucose, mannite and levulose from ten to six minutes. These are not to be taken as standards, but they are quite distinctive. Potassium permanganate in dilute sulphuric acid gives a still more rapid oxidation.

## VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 38, 39, 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 42 and 43. A short summary of vacant posts notified in the advertisement column appears in the *Supplement* at page 132.

## An Address ON THE APPROACH TO SURGERY

DELIVERED AT THE OPENING OF THE SESSION AT KING'S  
COLLEGE HOSPITAL MEDICAL SCHOOL

BY

SIR BERKELEY MOYNIHAN, Bt., M.S.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

THIS is Lister's year. One hundred years ago Lister was born. Fifty years ago this hospital had the courage to invite him to join its staff, and on the day of his inauguration Lister delivered this annual address at the opening of the winter session. At the centenary celebrations held in London in April and in Edinburgh in July much was said of Lister's work, of the revolution in surgery of which he was the sole and direct cause and of the unequalled services to mankind which he was privileged to render. Yet there remains, I think, something more to say, and what occasion could be more fitting than this—what platform more appropriate?

The story has often been told, and there is no need to repeat it here, of the horrors and tortures of surgery before the middle of the last century. The craft of the older men was possibly in some respects superior to our own, in swiftness of movement especially; they are said to have been almost incredibly expert. If only the cinema had then been able to record an amputation of the thigh performed by Lister or an excision of the jaw by Ferguson. I think we should all be as much startled at their rapidity as horrified at the general uncleanness, at the demonstrable absence of any conception of the truths regarding infection upon which all operative methods to-day are founded. Little wonder is there that surgery was likened to butchery. Lord Thurlow, when the bill to indemnify the Surgeons Compins, and to give it greater power over the profession, was under discussion said: "There is no more science in surgery than in butchery." To which Mr Gunning answered: "Then, my lord, I heartily pray that your lordship may break your leg and have only a butcher to set it." This was the same John Gunning who is said to have given that flat contradiction to John Hunter which acted like a sentence of death. Lister himself speaks of "the bloody and butcherly department of our art."

Surgery is in these days both Science and Art. As Science it accomplishes the purposes for which every science exists—to acquire direct knowledge, to accumulate facts from a multitude of individual examples to raise a broad truth, to weave generalizations, in its highest accomplishment to link cause and effect. We bring to our aid inductive and deductive logic, recalling with pride that both these weapons of the intellect were first brought into use and established by members of our own profession. For as Hippocrates was parent of the inductive, so was Galen of the deductive method. As Science surgery has not only separate existence but in its wider sense it is related to and dependent upon, many other sciences upon biology, chemistry, physics, physiology, and the like. Discoveries in these sciences not seldom react upon surgery whose progress has in the past often taken impulse from them whose progress cannot now continue without them. But surgery is not only a man's support, an applied science. If we could conceive it bereft of the aid of all other sciences surgery would still remain a science of exact observation of inductive reasoning, of pursuit and discovery of broad truths—a method of seeking the causes no less than the remedies of many of the diseases which afflict mankind.

As Art surgery is incomparable in the beauty of its medium in the supreme mastery required for its perfect accomplishment, and in the issues of life, suffering, and death which it so powerfully controls.

The methods by which surgery both as Science and Art, could be created, directed and expanded were fashioned in early days by Hippocrates and Galen but for more than a thousand years they were discarded. The works of the great masters were erected in the intellectual market-

places of the world as idols which all men must worship, or pay the price even with their lives. It is lamentable to realize that infinite harm may in the end be wrought by great teachers when their disciples slavishly imitate and perpetuate not the methods by which they won knowledge but their so fallible doctrines.

Men have not been reluctant to pay tribute to Lister for his incomparable services to the world, through the discovery of the principles underlying the modern practice of surgery, but they have been slow to realize that the eternal truths which he expounded are no less applicable in the domain of medicine. Infection plays a part also in the causation of those diseases which remain the province of the physician. First to discover and to propound this truth was William Hunter, who, in studying pernicious anemia in the year 1800, became convinced of its dependence upon oral infection. The connexion between these two conditions—between probable cause and tardy effect—seemed so slender, so incredible, that many workers did not even pay the tribute of inquiry. In medicine a new idea rarely obtains a friendly greeting at the moment of birth. We do well to be sceptical, to demand proof upon proof, and to seek evidence in our own experience before accepting a new doctrine. But when scepticism learns to hostility and is nurtured in derision we become worthy or blamo. Quick to resent Lister's contemporaries for their disdain and incredulity of our great master, we in our day are not free from numbing and sterile apathy. Since the year 1800 Hunter has fought with belated success for the recognition of focal sepsis as a cause of far distant and seemingly disconnected disease. To read his several papers to-day is to be convinced not only of the accuracy but of the far-sighted vision of his teaching. "A voice crying in the wilderness," and, like that other, we now realize that his too was teaching a true gospel.

It is not yet realized, I think, that Lister's work has not only revolutionized the scope and practice of surgery and revealed the clue to the so-long hidden mysteries of many systemic diseases but that it has also given to the surgeon and to the laboratory worker the strong instrument of research.

So rapid has been the advance of surgery so exacting the demand made upon those who practise it to train themselves in the manipulative skill necessary for the performance of newly conceived and newly designed operations, that in recent years few surgeons have found it possible to give adequate time to laboratory research. Surgeons have been regarded and have certainly too narrowly regarded themselves as mere execrants. They are in truth experimental biologists and in the last two generations have carried out valuable researches into the etiology, clinical manifestations, and therapy of disease. Their observations of the structural changes which in the human body cause the symptoms they sought to relieve have brought about a complete revision of our knowledge of visceral disease. Their work has been research in its highest form. It has been carried out upon the bodies of men. It has afforded eagerly taken opportunities for observing a host of new facts, it has exercised the faculties of induction and deduction. It has often linked unsuspected causes with remote effects. This it has done mindful all the while of the purpose for which it exists—alleviation or suffering or rescue of threatened life.

The story of the conquests of surgery to-day would be received with incredulity by Lister himself. It is not known that the master ever performed an abdominal operation, yet he it was who made all our triumphs possible. Before Lister's day the opportunities for investigating the processes of diseases in the patient's lifetime hardly existed, and the dangers of even the slightest experiment upon animals were so formidable as to be almost prohibitive.

Research in the science of medicine it is clear, is of two kinds—direct and analogical. Direct research is carried out by the surgeon as he conducts an operation. Analogical research is conducted upon animals or in the laboratory, and its chief purpose is to test, to illustrate, to interpret, to explain, or to expand the lessons learnt by direct research, or to explore the paths suggested by it. The difference between direct and analogical research in surgery is the counterpart of the difference which existed in Galen's day

between direct and analogical research in anatomy. Much of Galen's work is based upon observation of the structure of animals, by analogy this knowledge was applied to man. Are not the physiologists to-day perpetrating the very same error as our great forerunner? Are they not neglecting opportunities for direct research and too implicitly trusting to analogical research? Anatomy is a science applied to man was firmly established by Vesalius. Do we need in physiology to-day a Vesalius to lead us to the true faith? Why, when investigations into the normal processes of physiological activity or into aberrations from the normal can be conducted upon human beings, are so many opportunities neglected? Why are animals selected for the demonstration of certain physiological truths, and why are physiologists content merely to expound truths obtained by observation and experiment, when a visit to the wards would enable the teacher to imprint in indelible characters upon the minds of his pupils these same truths demonstrated upon the human body? Why are so many anatomists content to teach only on the dead body?

Lister made analogical research safer than ever before, but he was the one and only creator of direct research. His labours freed experiments upon animals from all the risks attaching to infection, and thereby powerfully increased the opportunities of the biologists. The new weapon of direct research upon man during remedial operations or after grave injuries was forged by him alone.

The simplicity of analogical research is of immense advantage. It demands ingenuity in devising and high technical skill in executing experiments, and intellectual honesty in observing and recording results. But the whole analysis of the experiment is objective. A plain answer is given to a plain question, and interpretation should offer few difficulties to the trained mind. In direct research, observations and their interpretation present perplexities which appear to be almost beyond the reach of analysis, for subjective sensation and complex emotional states are so apt to confuse the issue. Man, being a far more sensitive creature bountifully endowed with the gifts of expression, can tell us more of himself, of his discomforts, pains, and other manifold clinical occurrences, than any animal submitted to experiment. And elucidation, not only of facts directly observed, but of sensations of all kinds, their chances and changes, as experienced by the patient, is a matter requiring great industry, the skill of an expert cross-examiner, and a high degree of intellectual integrity free from all prejudice to appraise all matters with accuracy. He who is to carry out direct research should therefore first be trained in analogical methods.

For research into the conditions and causes of disease in man both methods of intellectual approach must be traversed. We need direct research to give us our first facts, to set the problem, through analogical research we seek the solution of our difficulties, in annotation upon our disclosures, and an analysis of individual factors in a complex problem wherein many are involved.

As an example we may take the subject of gastric and duodenal ulcer. Its submission to direct research has changed the whole front of our knowledge of this disease. Duodenal ulcer, indeed, except as a pathological entity, did not exist for the clinician until the surgeon revealed it. He created its clinical existence, differentiating it from those other diseases which so closely mimic it, he has devised the methods of its surgical treatment when it has proved recalcitrant. He has not only brought duodenal ulcer into the open, he has shown its frequency is compared with gastric ulcer, he has discovered something of its most impressive antecedents, he has studied conditions which coincide with, and perhaps contribute to it. Of the morbid anatomy of gastric ulcer we had learnt a great deal from William Billroth, Cruveilhier, Brinton, and others, but its clinical recognition was fraught with grave inaccuracy. Even to-day the diagnosis of "gastric ulcer" made upon clinical evidence alone is perhaps more often wrong than right. But clinical inaccuracy and bewilderment are at last yielding to patient research by the surgeon, ably supported by the radiologist. We are substituting truth for false-believe, gradually clearing away the multitudinous errors which have so long enumbered this subject. We seek to walk by sight, not by faith alone.

In surgery the hand of the beginner is heavy. In our earliest experience of gastric operations we found not infrequently that where a confident diagnosis of "gastric ulcer" or "duodenal ulcer" had been made, based upon the clinical knowledge of the times, the stomach and the duodenum showed no slightest lesion. A few little tags between the transverse meso-colon and the stomach were held to confirm the diagnosis, or a blanched area on the interior wall of the duodenum was regarded as the seat of a superficial ulcer. Gastro-enterostomy, so miraculously successful in case of obstruction at the pylorus, was then performed for at that time the short-circuiting operation was credited with almost magical therapeutic power. When the later history of such patients was traced the results were always indifferent or bad, sometimes lamentable. It was not long before I was driven to enunciate the doctrine that a chronic ulcer in need of surgical treatment only existed when it was "visible, palpable, demonstrable," and that surgical treatment should be adopted only when the presence of the ulcer was thus indubitable. I regret to find that in all countries there are still surgeons whose practice does not endorse this teaching.

When in my own work the "ulcer" so confidently diagnosed did not display itself, wider search was made as soon as this became safe, other abdominal organs being in turn scrutinized. The results of this extended inquiry were most interesting. We sometimes discovered a gall bladder full of stones, an appendix showing advanced disease, a group of tuberculous mesenteric glands, or, again, a patch of tuberculous ulceration in the intestine, large or small. Sometimes it was an enlarged spleen of splenic infarct, and, in rarest instances, a malignant growth of jejunum or colon. And so by degrees we were brought to realize the inaccuracy of many clinical descriptions of intra-abdominal disorders, and of the estimates of their relative frequency. We learnt that many diseases betrayed themselves by symptoms confidently ascribed to defects in organs other than that attacked.

For the vague, loose, inaccurate account of symptoms something approaching precision could now be substituted, to the great advance of our clinical knowledge. This extended research was soon made a matter of routine, and, to our surprise, isolated disease within the abdomen was found to be far less frequent than we had supposed. A patient suffering from a duodenal or a gastric ulcer, or harbouring gall stones, was discovered to have a diseased appendix. And it soon became evident that this association must not be regarded as accidental—that, indeed, the infection of the appendix was certainly the precursor and very probably the cause of pathological conditions present elsewhere. We now regard all ulcers and all gall stone, except the solitary cholesterol stone, as consequences of infection conveyed from a distance. William Hunter's thesis—his application of Lister's teaching to general medicine—was true here also. For it was rare to find any patient suffering from gastric or duodenal lesions in whom a focus of infection was not present, and the evidence is now, I think, incontrovertible that it is from such centres of infection that organisms are carried to far distant parts, then to induce a gross organic lesion, whose connexion with its cause seems remote and improbable, and whose symptoms completely overshadow those of the original infection if, indeed, these latter have ever been present.

If now, this subject is submitted to experimental analogical study we find, at first, that there is an insuperable difficulty in causing conditions identical with those observed in man. The chronic gastric or duodenal ulcer with their seasonal variations in activity—period of remission alternating with periods of violence, time of healing with times of destruction—do not occur, and have not yet been artificially produced, in any animal. But the cultivation of organisms from ulcers removed by operation has had interesting results. Rosenow's work upon the elective localization of microbes indicates that certain organs provide a more suitable culture medium than others, that there is affinity between soil and seed. He and his pupils Nickel and Hufford have shown that there is a green-producing streptococcus which, cultivated from specimens of gastric or duodenal ulcers removed by operation,

has an affinity for the stomach and the duodenum. After inoculation it causes hæmorrhage and ulceration in different species of animals. These analogical researches suggest that, though other factors doubtless are at work in addition to infection in leading to the development of an ulcer, they appear to be powerless to develop the chronic form of ulcer of the stomach or duodenum unless infection is added to them or precedes them.

Experiment and observation were never more happily united than in Lister's work. The discovery by Pasteur of the fact that fermentation was due to living micro-organisms was illustrated by Lister in a variety of experiments. The method of controlling or preventing the activity of microbes within the area of operation and within wounds was studied upon man—was in fact, a piece of direct research. One germicide or one mode of dressing after another was tested and for a time adopted only to be finally discarded or retained as clinical experience seemed to decide its value. For Lister realized that it is not merely killing of microbes which is to be desired, the problem is to render them inert within a wound without injury to the sensitive tissues of the body, whose helpful activities might be lessened or destroyed by the corrosive action of a germicide. A host of observers have laboured earnestly to discover new antiseptics, bactericidal power in contact with germs in a test-tube being regarded as the index or the proof of their chemical value. We know only too well how illusory are such beliefs. For the death-dealing power of a chemical agent *in vitro* is no measure of its full value in clinical work. Wound secretions add a new factor to the problem. Indeed I have little doubt that as far as wound applications are concerned, the value of an antiseptic is not to be gauged by its bactericidal but rather by its antitryptic power. We do not so much seek to kill germs within a wound as to encourage the wound in its process of resistance to their attacks—to exalt the natural bactericidal power of wound discharges. This is perhaps not the best but at the moment it is the most apposite of the illustrations which might be given to show the mutual interdependence of clinical and laboratory work of direct and analogical research. To the clinician this needs no demonstration but I fear the laboratory worker is in danger of becoming a little too eager to exert dominion in territory which his skill has not yet conquered. Lister's work is now being enlarged and perhaps completed by Almroth Wright, who by his study of immunity has made it clear that whereas Lister sought only to diminish or to destroy bacterial attack, success may also be found in our increased defence against microbial invasion.

The changes that have taken place in surgery, the great increase in the number, intricacy, and scope of operations, have made it far more necessary than ever before that the surgeon should be a skilled craftsman. To practise the craft with something near perfection a man must surrender his whole life. To attain a certain facility in operative work is not difficult to imitate the master's methods and to follow the movements of his skilled hands is within the easy competence of many. Man Aristotle tells us, is the most imitative creature in the world, and learns at first by imitation. It is natural for us all to delight in works of imitation, but in imitation there lies a great danger. Many of the operations in surgery have now become so standardized, so perfected and simplified by a multitude of workers, that they can be imitated by others with a degree of success which, though falling short of the best, is yet, by comparison with the results of a generation ago, worthy of high praise. Thus has unhappily led to the too frequent performance of operations and to their performance by those whose judgement has not kept pace with their technical accomplishments. Perhaps the most abused operation in surgery is gastro-enterostomy. A distinguished Continental surgeon has fathered a paper by one of his pupils on "gastro-enterostomy a disease." The anastomosis is in all truth a disease when performed in the absence of a sufficient cause or in an artistic and vicious manner. That it is frequently performed when no need for it is performed by the clumsiest imitator, is certain. Many of us have read the bitter duty of undoing such anastomoses or of resecting the ulcer which has developed in consequence of them. The physician who sees

such cases condemns the operation in that, such, it is wrong, his strictures and ours should fall not upon the operation but upon the operator. I conceive that a duty rests upon the physician greater than he realizes. When a physician for whose talents and devotion I have great respect expressed his regret that he could not agree with my advocacy of surgical treatment for chronic intractable duodenal ulcer because the mortality of the operations practised upon his cases was over 10 per cent, I was constrained to say that were the mortality in my hands so high I should abandon surgery. The duty rests upon the physician, if he advises operation, to point out that the mortality of operative work varies with the operator, that though in general terms there is an average mortality for every operation, in cases of difficulty or danger where the fine issues between medicine and surgery must first be decided and much depends upon experience the choice of a competent and practised operator is necessary. Many of us, I suspect, are at times placed in very difficult positions. A patient is sent for our opinion as to whether an operation shall be performed for a certain condition and the medical man or the patient himself tells us that in the event of an operation Mr. Blank will perform it. We may agree with the diagnosis, we may agree that an operation is certainly necessary, and we may know that the suggested operator is by no means a wise choice. If it is true that all patients cannot have the best, all ought at least to have the best possible.

There is no doubt that a change in the training of the surgeon is imminent and is certainly overdue. What should be the approach to surgery? It has long been the custom for those waiting to obtain a post on the surgical staff of a hospital to spend months or years in teaching anatomy. And what anatomy have they been compelled to teach? "Descriptive anatomy" the bare record of the physical characters of the various structures of the human body. Students, in accord with modern custom must be taught the origin and insertion of muscles, the origin, course, branches, and destiny of nerves, the source, divisions and direction of vessels and the like—a dull catalogue of dead things. For descriptive anatomy has in all countries of the world for a century been divorced from functional anatomy. Sir Arthur Keith has told the story of this lamentable secession. The early English anatomists from William Harvey onwards were not content merely to say in words what any man could see with his own eyes. They were deeply concerned not only with the appearance of parts but with the meaning attached to structure. They tried to know not only how organs of the body were constituted but why they were so made. Their interest was engaged by the function no less than by form. John Hunter was intensely occupied with dissection hardly a day passed without his spending many hours in studying the anatomy of parts in man and in various animals whose bodies he could beg borrow or steal. But he sought to know not merely what and where the various structures were but even more the function they fulfilled. For him as Keith says 'it was not enough to recall that the wall of the aorta was twice as thick as that of the pulmonary artery, or that the walls of some veins were thick and of others thin, he immediately set to work to find out the significance of these facts. He appealed to comparative anatomy, to embryology to pathology and experiment for an explanation.' In February next we will be the 200th anniversary of John Hunter's birth and we hope then to display Hunter's own handiwork in such manner as to show the variety of his intellectual appetite and his unsurpassed skill in dissection. But dissection was always a search for the reasons of the actions of parts not merely for their structure.

How then did anatomy go astray? Keith rightly traces the catastrophe to the influence of France and to the delightful gifts of our Gallic colleague for systematic and logical thought with orderly and luciferous expression. It seems that the determining influence was that of Winslow (1669-1760) professor of anatomy in Paris. His teaching recounted the best in Europe was eloquent for all to hear. "Whilst merely conveying to his learners or readers what they might see with their own eyes, at a glance he left them with the pleasant impression that they were drinking

at the very fountain-head of pure knowledge." He purposely abstained from attempting to explain the meanings of the structures he described, and in doing so impoverished the study of anatomy. The standard set by him was universally followed, and was to find its highest expression in one of his successors—Biehn (1771-1892). At the time when I became a student, forty-four years ago to-day, we were taught anatomy as we should be taught the plan of a city, learning the names of houses, of main streets, of their branches and turnings, by whatever gate we entered we thus learned to find our way about. But to the people who lived in the city, their industries, their way of life, the part they filled in the community, we were hardly expected to give a thought. For all we knew the city might be dead.

It is true that the surgeon must know the formal anatomy of the human body—no very difficult attainment, though he will sometimes find that he still must make his own fresh investigations. When, for example, certain problems presented themselves in connection with the operative treatment of gall-bladder disease, my colleague Mr. Flint, at my suggestion, examined in the *post-mortem* room 200 bodies, and was able to teach us new truths relating to the vascular supply of the gall bladder and the anomalies of the ducts of the liver. But to be constrained by custom to teach successive generations of students the details of descriptive human anatomy, to be compelled day after day, year after year, to restrict one's teaching to the elementary parts of a finite subject, human anatomy, is insidiously to develop an intellectual complacency, a feeling that one is master of one's subject. Nothing so easily destroys a man's capacity for thought and his delight in indulging it (it is, alas! sometimes a torture) as the restriction of his mental efforts to a limited part of a subject now hardly capable of extension. It is difficult to imagine any training less fitted in these times for the young surgeon. Anatomy as an approach to surgery cannot long continue to be the descriptive anatomy of recent years, a sterile derivative of true anatomy which embraces a study of functional activities and purposes. We must return to the anatomy of the English school, the science founded by Harvey and pursued by Hunter, Charles Bell, and Lister: the science which stretched in the Aristotelian phrase for "final causes," and which tried to answer the question "To what end?" In my days I did my best to escape from the insipid routine teaching of anatomy by devoting a part of almost every day to original work in the *post-mortem* room and in the dissecting-room, and upon foetuses which I besought my friends in general practice to send me. I worked upon the subject of internal hernia, and upon the rarer forms of external hernia. And I was saved from the cramping influences of the dissecting-room by the surprising desire of many medical men to surrender their patients to my immature skill at a time when abdominal surgery, having survived the dangerous pioneer period through which it had just been steered by Spencer Wells, Lawson Tait, and Mayo Robson, was at length becoming so safe that many diseases hitherto beyond the reach of the surgeon were now being successfully attacked.

But all my life I have wished that my training had been different. Were my days to come again I should, after leaving examinations behind, spend the time necessary to make an adequate knowledge of human anatomy my permanent possession, and should then escape to experimental research and in a community of like minded people, endeavor to train myself for the high destiny of a surgeon, the one man who may engage in direct research. My time would be spent in the laboratory, where a youth of plastic mind may learn the methods of approach to new problems or to new extensions of old problems, where old knowledge is merely an impulse to the search for new, where intellectual dissatisfaction is victor over narrow complacencies, where the religion of research inspires him and equips him for his work in days to come. If surgery is to be something more than a wonderful craft, if it is to be the instrument of research which I believe it to have been, and to be destined to be in the future, those who practise it must have their minds shaped and strengthened by conflict with unsettled problems, not cramped and sterilized by mono-

tonous exercise within a narrow province of static knowledge. Their minds must be trained in the laboratory, in an original research, so that they may be more effectively exercised both in the operation theatre and in the ward, upon direct research, not, I need hardly say, to neglect of the dissecting-room, but to its relegation to a subordinate position. The comradeship of laboratory workers and clinicians should be intimate and unbroken. The scientist at work in the laboratory can never reap the full reward of his lonely researches without close and loyal collaboration with the clinician. Nor can those who serve the same cause in a different atmosphere give to their patients the best aid of medicine and surgery without the help of the scientist. The training of the surgeon must not only allow, it must urge, his mind to stray beyond the hard boundaries of old knowledge, over the edge of firm beliefs, into wide territories as yet unexplored and even undivined. In this way only is there escape from the danger which besets the surgeon in the future, the peril of a facile automatism. In this way may the physiologist be brought back from his vagrancies and encouraged to realize that his science best fulfils its destiny when it is applied to the understanding of the functions, normal and aberrant, of the organs of man. It is a delight to me to see that a few of the younger surgeons in this country are taking the path which I should follow if I were on the threshold of a surgical career.

Lister was thrice, four times, happy in growing up under the sway of men steeped in the old ideals of anatomy. The intellectual influences of his life came from Sharpey and from Wharton Jones—duty, despised, yet passionate in his zeal for the discovery of truth by way of observation upon living structures. Like their teacher, Alexander Monro (*secundus*), these men never wearied in the search for reasons. They were not content with mere knowledge of the construction of parts, but in that knowledge sought the clue to the several actions of which those parts were capable. In Lister's early paper, "Observations on the contractile tissue of the vis," "On the muscular tissue of the skin," "An inquiry regarding the parts of the nervous system which regulate the contraction of the arteries," "An inquiry into the functions of the visceral nerves," we see clearly that he was carrying on the high tradition in which he was trained. I have not gained the impression that Lister was a man of really exceptional intellectual gifts. Rather he was a man of great intelligence trained in the very manner which helped his mind to work to highest advantage in his special calling. Advances in medicine and surgery are made by men who to the faculty of observation add the power of conceiving and carrying out experiments, not in the laboratory only, but also in the operation theatre and in the ward. For disease and accident alike may be regarded as beginning experiments for us, and it is for us to add factors of our own devising, to exert influences designed to check or to change the course of events, and, in so doing, to judge both causes and effects and the range of our power over both.

No training of the surgeon can be too arduous, no discipline too stern, and none of us may measure our devotion to our cause. For us an operation is an incident in the day's work, but for our patients it may be, and no doubt it often is, the sternest and most dreaded of all trials, for the mysteries of life and death surround it, and it must be faced alone. Those who submit to operation are confronted, perhaps after long and weary days or months of suffering, with the gravest issues, and far more often than many of us suppose they pass into the valley of the shadow of death, and, in stark dismay, wonder with Beatrice in her chilling solitude and pain what will come to pass.

"If there should be  
No God, no Heaven, no Earth in the void world,  
The wide, gray, lampless, deep, unpeopled world,"

To give courage to those who need it, to restore desire for life to those who have abandoned it, with our skill to heal disease or check its course—this is our great privilege. Ours are not the mild concerns of ordinary life. We who, like the Happy Warrior, are "doomed to go in company with Pain and Fear and Bloodshed" have a higher duty than other men, and it is for us to see that we are not unworthy.

## TUBERCULOSIS OF THE KIDNEY\*

BY

SIR JOHN THOMSON WALKER, M.B. C.M. I.P.C.S.,  
Lecturer on Urology, King's College Hospital

Tuberculosis of the kidney illustrates the advance in diagnosis and treatment in renal surgery in the last twenty-five years. The mortality of nephrectomy for tuberculosis of the kidney between 1890 and 1900 was 25.4 per cent.

At that time no adequate means of ascertaining the presence and condition of the second kidney were generally employed. The use of the ureteral catheter and the test of the renal function, together with a more accurate knowledge of the pathology of renal tuberculosis have reduced the operation mortality to 2 or 3 per cent.

## SURGICAL PATHOLOGY

Renal tuberculosis is a disease of young adult life and occurs most frequently between the ages of 20 and 40. It is rare in children, and in them is more frequently bilateral in the early stages. The disease is uncommon over 50 years, and at this age is more chronic than in middle life. The male sex is more frequently affected than the female in a ratio of about 2 to 1. In adults chronic renal tuberculosis is unilateral in from 80 to 90 per cent of cases in the early stage.

## Source and Route of the Infection

In the strict meaning primary tuberculosis of the kidney cannot be said to exist. A primary focus is always present elsewhere in the body, although it may not be discovered clinically. Biarsch places the coincident lesions discovered in 346 operated cases at 71 per cent. Others have found a lower proportion of coincident lesions in clinical work. Thus Persson\* states the figure at 50 per cent and in 193 cases operated on by himself 48.1 per cent had evidence of obsolete tubercle elsewhere in the body.

A history of pleurisy and clinical evidence of obsolete pulmonary tuberculosis is common, while *post-mortem* evidence shows that tuberculous glands of the mediastinum are present in a large proportion of cases. Active pulmonary tuberculosis is found coincident with renal tuberculosis in a small number of cases (5.3 per cent).

Tuberculous lesions—which must equally with renal tuberculosis, be secondary—are found in other parts of the body. The exact relationship of these to the renal lesion is not always clear, but some of them may be the immediate source of the tubercle bacilli that infect the kidney. In order of frequency these are genital tuberculosis in the male and tuberculosis of bones and joints. In my cases submitted to operation there were tuberculous lesions of the epididymus in 23.3 per cent, of the prostate in 15.3 per cent, and of the seminal vesicles in 7.3 per cent.

There are three possible paths—namely, the ascending or urinary by the lumen of the ureter, the lymphatic and the haematogenous.

There is experimental evidence that, under certain conditions, ascending infection by the lumen of the ureter may occur (Wildbolz†) there is histological evidence that lymphatic infection along the ureter may take place (Bauerstein,‡ Walker§) and there is pathological evidence that supports lymphatic infection from the thorax (Brongersma¶). The weight of evidence at the present time supports the view that in renal tuberculosis the tubercle bacilli are blood borne.

## VARIETIES OF RENAL TUBERCULOSIS

It is possible to reduce the many varieties of renal tuberculosis that have been described to three: (1) *milary tuberculosis*, (2) *chronic renal tuberculosis*, and (3) *tuberculous nephritis*.

## Milary Tuberculosis

This is an acute condition in which both kidneys are strewn with tubercles. It is part of a general tuberculosis and is of no surgical interest.

\* A paper read in opening a discussion on this subject in the Section of Surgery at the Annual Meeting of the British Medical Association at Edinburgh.

## Chronic Renal Tuberculosis

Under this head are included almost all forms of renal tuberculosis that come under the care of the surgeon. It includes the conditions known as apical tuberculosis, ulcerovascular tuberculosis, tuberculous hydronephrosis, caseous tuberculosis, nodular tuberculosis and tuberculous abscess.

The first change in the great majority of cases takes place at the apex of a pyramid. There is a small loss of substance surrounded by a zone of inflammation. The ulceration spreads outwards towards the base of the pyramid, and a cavity communicating with the calyx is formed. The lining of the cavity is a layer of necrotic or caseating tissue. Beyond this is a zone of inflammation which may show grey tubercles and occasionally there is a complete zone of grey gelatinous tubercle. Onward from the zone of inflammation isolated tubercles are dotted in normal renal tissue or arranged as one or more streaks radiating to the surface of the kidney. On the surface of the kidney groups of tubercles are seen in areas corresponding to the subjacent tuberculous pyramids. One or several, or all the pyramids may be affected in different degrees. Another pathological process may now become prominent in the wall of the calyx at its neck or the division of the pelvis at its outlet or in the wall of the pelvis fibrous thickening develops and contracts until the passage is finally occluded. If now the urinary secretion in the section that is gradually being occluded is maintained a localized cyst or partial or total hydronephrosis develops. If, on the other hand the secretion of urine is abolished a caseous mass surrounded by fibrous tissue is formed and the whole kidney may be converted into a mass of the caseous masses. The ureter is greatly thickened and rigid in a large proportion of cases. There is ulceration, necrosis and caseation of the mucosa and tuberculous infiltration with the formation of thick layers of fibrous tissue in the middle and outer coats. Stricture formation may affect one or several parts of the tube and dilatation of the tube occurs above.

## Tuberculous Nephritis

In cases of pulmonary tuberculosis the urine may contain albumin and tube casts and the same may also be present in the urine of the second kidney in chronic renal tuberculosis. In the latter condition the symptoms usually clear up after removing the tuberculous kidney. This condition has been regarded as due to toxic nephritis and *post-mortem* examination has shown that there was either interstitial or parenchymatous nephritis but that tuberculous changes were absent. Recently Heim† and others have described kidneys where nephritis of this character was present and tubercle bacilli were found in the kidneys without any specific tuberculous changes. In a woman aged 37 I removed the left kidney for intermittent haematuria when no bacilli were present in the urine. The kidney was small and showed interstitial nephritis and minute cysts and scattered throughout were giant celled systems. This case might be regarded as unilateral chronic *milary tuberculosis* of the kidney.

## SYMPTOMS

The symptoms of renal tuberculosis do not at first and may not at any time directly refer to the kidney. I have placed them in the order of frequency in which they occurred in the cases under my care: (1) bladder symptoms, (2) changes in the urine, (3) loss of weight, (4) haematuria, (5) renal pain, (6) palpable renal swelling and thickened ureter.

In the majority of cases irritability of the bladder with increased frequency of micturition is the first and for a long time the only symptom of which the patient complains. The irritability is slight and variable depending on the weather and diet. It increases until urine is passed every twenty or thirty minutes day and night accompanied by pain before and after micturition. The urine in the early stage is increased in quantity, it is pale, faintly acid or neutral and contains albumin and a small amount of suspended pus and fine white flakes. In uncomplicated cases a few tubercle bacilli are found, but no other bacteria.

Slight terminal haematuria is frequently observed, and an attack of haematuria is occasionally an early symptom.

Rarely, severe attacks of hæmaturia are a prominent feature. Continuous slight loss of weight is as a rule observed, but there is no rapid or severe emaciation in uncomplicated renal tuberculosis. Renal pain is usually insignificant, and may be entirely absent. With severe hæmorrhage there may be ureteric colic from clots. Fever is absent in most cases, but a slight persistent rise of temperature to 99° or occasionally to 100° F. may be observed. A high temperature, if present, is a symptom of either a mixed infection or of general tuberculosis. The kidney is felt enlarged in a small number of cases of uncomplicated renal tuberculosis. Even when it is considerably enlarged it may be adherent high up under the diaphragm and not be felt.

A thickened tuberculous ureter may be detected on deep palpation at the level of the bim of the pelvis in a thin subject, on rectal examination in the male subject, or as a thick cord in the lateral fornix on vaginal examination. It is a characteristic of renal tuberculosis that the disease may have advanced so far as completely to have destroyed one kidney without causing symptoms that attract the attention of the patient. The symptoms may vary, and in some cases may disappear for considerable periods. In the majority of cases, however, the symptoms are slowly progressive.

#### SPONTANEOUS CURE AND CLOSED RENAL TUBERCULOSIS

A condition of clinical importance has received the name of "closed renal tuberculosis" or "autonephrectomy." The latter term is incorrect and unscientific. With this, and inseparable from it, must be discussed the question of spontaneous cure of renal tuberculosis.

A tuberculous lesion of the kidney may be arrested as the result of one of two processes—namely, (1) healing of the tuberculous lesion with disappearance of the tubercle bacilli and replacement of the ulcer by a scar, and (2) exclusion of the tuberculous focus by a ring of fibrous tissue.

I have searched for many years in the kidneys I have removed for tuberculous and other diseases for evidence of healing of a tuberculous lesion without destruction of the segment of the kidney affected or of the entire kidney. I have only met with one example, and this, although it appeared perfectly healed to the naked eye, still showed some giant cell systems microscopically.

In this case I removed the right kidney of a woman, aged 40, for acute hæmatogenous pyelonephritis due to staphylococcal infection. One of the pyramids in the middle third of the kidney showed the apex cleanly scooped out. The calyx was normal and to the naked eye there were no signs of inflammation. The lining of the cavity was smooth. The pathological report was as follows: "The cavity which occupies the position of the apex of a calyx is in part lined by epithelium like cells, but at one spot the lining is composed of granulation tissue in which a few giant cells are still to be found. Apart from this there is no evidence of tubercle."

2 The form in which the activity of a tuberculous lesion of the kidney is arrested by exclusion of the focus is not uncommon (10 per cent of renal tuberculosis—Briarsch<sup>1</sup>), and has received the clinical name of "closed renal tuberculosis." It was first described as a clinical entity by Zuelcher and Lind,<sup>10</sup> and later described fully by Smirnov.<sup>11</sup> I have seen three varieties of change in the kidney that have produced this clinical phenomenon—namely, (1) tuberculous hydronephrosis, (2) massive caseous tuberculosis of the kidney, and (3) occlusion of an ulcer-cavernous focus. The whole of the kidney, or only a part of it, may be affected by the closure.

#### Clinical Aspect of Closed Renal Tuberculosis

In some cases of renal tuberculosis there has been bladder irritability for a time, but this has been neglected and has disappeared, and the condition known as closed renal tuberculosis, where the infected area is shut off from the urinary tract, has developed. No further symptom may arise, and the presence of a closed tuberculous kidney may be unsuspected during the life of the patient and be accidentally discovered after death.

The discovery of closed renal tuberculosis may be made during the routine examination of a candidate for life

insurance, or during the investigation of some condition independent of the urinary disease. Examination of the urine and x-ray examination and cystoscopy are the methods by which attention is drawn to the renal disease. There may be albuminuria, or a trace of pus, or some red blood corpuscles, and the x rays may show the shadow of caseous masses in the kidney. The kidney may be enlarged, and a thickened ureter may be felt on abdominal, rectal, or vaginal palpation. Cystoscopy and chromocystoscopy show a closed and dragged out ureter. The discovery of closed renal tuberculosis on one side may be made during the examination of a case of tuberculosis of the other kidney.

When the closed focus affects only a part of the kidney the diagnosis becomes very difficult, and may be impossible apart from operation. The x rays and pyelography may, however, give information that leads to a diagnosis. Closed tuberculosis in one part of a kidney with retro open tuberculosis affecting the remaining portion of the organ is not uncommon, and accounts for the variation and even temporary disappearance of symptoms.

A very important question arises in regard to these cases of "closed renal tuberculosis." Is the tuberculous infection of these kidneys permanently inactive, or is it still potentially active? Where one portion of the kidney is the seat of "closed tuberculosis" the remaining part of the kidney may continue to function and remain healthy, and at a later date become infected with tubercle. I removed a kidney where the upper one-third was a closed tuberculous hydronephrosis and the apex of one pyramid of the lower third showed early tuberculous ulceration. There had been a trace of pus but no bacteria found in the urine seven years previously. For nine months before operation there was loss of weight, pyuria, and tubercle bacilli in the urine.

Infection of the urinary tract may occur from a tuberculous focus which has been closed. In the following case the exciting cause of the reopening of the tuberculous focus was an injury.

A man, aged 40, had had hæmaturia fifteen years previously. Three weeks before I saw him he fell heavily down a flight of stairs. Six days later frequent micturition and hæmaturia suddenly developed and the urine was found to contain tubercle bacilli. The left ureter was oedematous, and near it was a small patch of tubercles.

Nephrectomy showed a large kidney converted into a series of round cysts, and at the lower pole there was a tuberculous cavity communicating by a narrow neck with the pelvis. Acute inflammation of the pelvic mucous membrane spread from this opening into the lower part of the pelvis and down the ureter.

Persson mentions a case where a fracture of the pelvis was followed by miliary tuberculosis and an autopsy revealed an unsuspected renal tuberculosis. Briarsch investigated five kidneys the seat of closed renal tuberculosis by inoculation of guinea pigs and found that in four the tuberculous infection was dead in one it was still active. Wildbolz found in the wall of a closed renal tuberculosis fresh tubercles in spite of the fact that the contents were sterile. In a case described by Kapsammer<sup>12</sup> spontaneous healing had lasted for many years, but eventually a perinephric abscess developed and caused death.

These cases show, and the experience of other observers confirms the view, that closed renal tuberculosis is a potential source of further infection.

#### DIAGNOSIS

##### 1 Symptoms

The spontaneous development of signs of cystitis is insidious in its onset in a young adult suggests the presence of urinary tuberculosis. Discomfort, pain, and tenderness of the kidney, and enlargement of the organ, may be present. These symptoms do not, however, necessarily prove that this kidney is tuberculous or that the other kidney is healthy. The symptoms may arise in a kidney which is hypertrophied and healthy or recently infected with tubercle when the other kidney has been destroyed by tubercle without any symptoms being noticed by the patient.

##### 2 Aseptic Pyuria and Albuminuria

Where there is pyuria and the urine is sterile it is practically certain that tuberculosis is present. Pyuria may be absent in closed renal tuberculosis. Albuminuria is a constant symptom, and its absence will raise a doubt as to whether tuberculosis is present even when other signs point to the condition.

### 3 The Tubercle Bacillus

The discovery of the tubercle bacillus is the final proof of urinary tuberculosis. The proportion of cases in which the bacillus is found in the urine is given by Persson as 65 per cent, by Beer<sup>12</sup> as over 70 per cent, and by Wildholz as 90 per cent. Hattinger<sup>14</sup> found the bacillus forty two times in the first smears and six additional times in second smears, and only failed in four cases. The tubercle bacillus is usually present in small numbers, and there may be a difficulty in finding it, so that repeated examinations are required. Hyman and Mann<sup>15</sup> state that large numbers of bacilli are more likely to be found in the earlier than in the later stages of the disease. Animal inoculation should always be made where a doubt exists.

In regard to the discovery of the tubercle bacillus in urinary tuberculosis we must contemplate two possible conditions: (a) the tubercle bacillus is not demonstrated but the symptoms point to tuberculosis, (b) the bacillus is demonstrated but other proofs of tuberculosis are wanting.

#### (a) The Tubercle Bacillus is not Demonstrated

Failure to discover the tubercle bacillus in the urine does not exclude urinary tuberculosis. In 295 cases of proved tuberculosis of the kidney Persson found that the tubercle bacillus was demonstrated microscopically in 78.3 per cent and by guinea-pig inoculation in a further 7.1 per cent—in all 85.4 per cent of cases. In 193 cases in which I performed nephrectomy for renal tuberculosis the tubercle bacillus was found in the urine in 155 (80.3 per cent). There are several reasons for the failure to demonstrate the tubercle bacillus in 20 per cent of cases of renal tuberculosis. The search must be made by a competent bacteriologist and much time and care must be spent on it, the number of bacilli may be very small and their appearance in the urine intermittent, repeated search in specimens taken at different times is therefore necessary. Again, the tuberculous focus may be shut off from the urinary tract (closed tuberculosis), when the renal lesion is closed but there is tuberculous ulceration of the bladder repeated examinations frequently fail to discover the tubercle bacillus, and the same may be true when tuberculous ulcers persist in the bladder after nephrectomy. Finally the tubercle bacillus may not be pathogenic to the guinea-pig. Cases of renal tuberculosis in man have been described by Lowenstein<sup>16</sup> and Joannovic where the bacillus of fowl tubercle has been found. This type of tubercle bacillus is non-pathogenic to guinea-pigs. Hryntschak<sup>17</sup> ascribed the failure to discover the tubercle bacillus to this cause in some cases of human tuberculosis of the kidney.

In cases where the tubercle bacillus is not demonstrated in the urine the diagnosis may be made by the symptoms, the presence of tuberculous lesions elsewhere in the body, and especially in the male genital system, the discovery of a thick ureter, the demonstration of x-ray shadows thrown by caseous masses in the kidney, or by the help of cystoscopy. In 58 of my 123 cases the tubercle bacillus was not found in the urine and the diagnosis was made by the cystoscope in 30 of these (15.5 per cent).

#### (b) The Tubercle Bacillus is Present in the Urine

The demonstration of the tubercle bacillus in the urine is usually regarded as diagnostic of tuberculous disease of the urinary tract. The tubercle bacillus may be discovered in the urine when no other symptoms of urinary tuberculosis are present—a condition termed 'tuberculous bacilluria'.

In such cases the question arises, whether a lesion of the kidney insufficient to give rise to symptoms exists or whether it is possible for tubercle bacilli to pass through the kidney without producing a focus of tuberculous disease.

Foulerton and Hillier<sup>18</sup> were the first to show that tuberculous bacilluria without a tuberculous lesion of the kidneys might occur in cases of pulmonary tuberculosis. Kiellenthal<sup>19</sup> confirmed the observations of Foulerton and Hillier, and proved that in his case no genital source for the bacilli existed. Hoob<sup>20</sup> found tubercle bacilli in the urine of 6 per cent of phthisical patients. Kiellenthal found that in all cases where a tuberculous bacilluria was

present there was albumin in the urine, and other observers have noted the presence of albumin and tube casts.

It seems probable, therefore, that a non-specific nephritis is present in all cases where tuberculous bacilluria is found. The bacilluria in these cases is probably not continuous, and may have a short duration. Nitch relates a case where tuberculous bacilluria was found in clear urine, and continued for two and a half months and then ceased, and the patient was well eleven years later.

The presence of the tubercle bacillus in the urine cannot of itself be regarded as a proof of tuberculous disease of the kidney. In clinical work the additional proof required of a tuberculous lesion in the kidney is the presence of pus in the urine. When pus is present even in microscopic amount, it is proof that there is a tuberculous lesion, where it is absent and closed tuberculosis can be excluded there is no surgical tuberculous lesion of the kidney.

### 4 Complement Fixation Reaction

Dr Megumi Takahata<sup>21</sup> has recently reviewed the value of the complement fixation reaction of the urine in urinary tuberculosis and found this test accurately indicated the affected kidney in unilateral renal tuberculosis. Kilbane used the von Pirque test and found it positive in 8 out of 10 cases of renal tuberculosis. In the great majority of cases the accurate methods of diagnosis render these tests superfluous, but cases may occasionally arise where the complement fixation test may be of value.

### 5 Cystoscopy

It is frequently possible by means of the cystoscope alone to diagnose renal tuberculosis. Changes easily recognized by the trained observer occur at the ureteric orifice and in the bladder. In 20 of 193 cases in which I performed nephrectomy for renal tuberculosis the diagnosis was made by the cystoscope, search for the tubercle bacillus having failed. Space does not permit of a description of the cystoscopic appearance in the bladder.

While examination of the ureteric orifice usually gives definite information as to the presence of tuberculous disease of the corresponding kidney there are cases where this may be unreliable. The ureteric orifice may be normal when the kidney is infected and on the other hand, the ureteric orifice may be involved in an area of tuberculous inflammation of the bladder and the kidney be free from disease.

The observation of a stained ureteric efflux by cystoscopy after injection of indigocarmine (chromocystoscopy) has little value in deciding whether the kidney is tuberculous. A deeply stained efflux may be seen when the kidney is infected.

### 6 Catheterization of the Ureters

By catheterization of the ureters a specimen of urine is obtained from each kidney. If one ureteric orifice is definitely tuberculous only the apparently healthy side need be catheterized but where a doubt exists both ureters are catheterized. The urine so obtained is examined for (1) the presence of the tubercle bacillus (2) other bacteria, and (3) the functional power of the kidney.

There are cases of advanced tuberculosis of the bladder where the ureteric orifices are involved in the inflammation and ulceration and it is impossible to pass a catheter into the ureter. Several courses are open to the surgeon. He may await improvement in the bladder condition under the influence of tuberculin. This is problematical. The bladder may be opened and the ureters catheterized through the cystotomy wound. I have found this a difficult and unsatisfactory method with little advantage over cystoscopy. Bilateral nephrotomy is recommended by some surgeons. In practice the method is not satisfactory. A tuberculous lesion situated at the apex of a pyramid is difficult—and may be impossible—to see when the kidney is opened by nephrotomy. The damage to the kidney is a grave disadvantage when its neighbour is tuberculous.

Fullerton recommends that the ureter should be exposed at the brim of the pelvis by a muscle-splitting operation in the lower iliac region. The ureter is incised and a catheter pushed up to the kidney and a specimen obtained, after which the wound in the ureter is closed with fine

cutgut. If the ureter is found diseased it is not opened. I have used this method in a number of cases and found it extremely valuable. The exposure is not difficult, and I have had no trouble with healing after the operation.

### 7 X-ray Diagnosis

According to Braasch<sup>3</sup> 20 per cent of cases of renal tuberculosis have positive x-ray data of definite diagnostic value. Small irregular shadows may be found in the kidney area. They are thrown by caseous areas in a tuberculous kidney and are sometimes confused with stone shadows. The outline of these shadows is irregular and the density low and uneven. A heavy uniform shadow is thrown by a caseous mass in the kidney. In massive caseous tuberculosis of the kidney there is a closely set mosaic of rounded or oval shadows.

A thickened tuberculous ureter containing caseous material sometimes throws a shadow. Pyelography is occasionally used to estimate the extent of the tuberculous disease. The outline of the affected calyx or group of calyces is enlarged, blurred, and indefinite, and the pelvic outline may be irregular and the cavity dilated. It is only justifiable in rare cases.

### TREATMENT

The modern treatment of renal tuberculosis is nephrectomy in all cases where the second kidney is healthy and no definite contraindication exists. This treatment is based on three postulates of the surgical pathology of chronic renal tuberculosis.

- 1 Tuberculosis of the kidney is a progressive disease.
- 2 Tuberculosis of the kidney is unilateral in the early and bilateral in the late stage.
- 3 Removal of the tuberculous kidney prevents in most cases the infection of the second kidney.

Space does not permit of further discussion of these points.

As regards operation only nephrectomy need be discussed. Partial nephrectomy has been abandoned on account of the difficulty of ascertaining on the operation table how far the disease has invaded the kidney. Nephrotomy is only performed when nephrectomy is impossible.

### Indications and Contraindications for Nephrectomy

1 *Extra-urinary Tuberculous Disease*—Obsolete tubercle in other parts of the body (lungs, spine, or joints) is no contraindication to nephrectomy and has no adverse effect on the after-history of the case. When active tuberculous disease of bones or joints is present operation on the kidney should be postponed until the extra-urinary tubercle has been successfully treated. Where active tuberculous infection of the lungs is present operation on the kidney is contraindicated. Tuberculosis of the male genital organs (epididymis, prostate, and seminal vesicles) does not contraindicate nephrectomy. In several cases I have removed both epididymes, the prostate and the seminal vesicles, and the kidney with complete success.

2 *Bilateral Renal Tuberculosis*—The removal of the kidney in which the disease is more advanced in bilateral tuberculosis is advocated by some surgeons. According to those surgeons active hyperaemia of the remaining kidney follows nephrectomy, which increases the resistance to the tuberculous infection. The tuberculous lesions become more localized and there is a greater tendency to connective tissue formation. In some cases cure of the condition is claimed.

Ekhorn<sup>4</sup> in bilateral renal tuberculosis exposed both kidneys and removed the more diseased of the two. In 20 cases the immediate result was diminution of pain and pyrexia. Subsequently 10 died, 5 were still alive, and 5 not traced. Two of the survivors were free from pain and able to work twelve years after operation and a third five years after operation.

Braasch<sup>5</sup> reports 13 deaths within one and a half years following nephrectomy in 16 patients with bilateral disease. In a series of 62 bilateral cases Israel<sup>6</sup> found about 70 per cent had died shortly after the nephrectomy.

The immediate post-operative mortality of nephrectomy in bilateral tuberculosis varies from 66 to 80 per cent, and the benefits gained in the few surviving cases have not been permanent. The procedure is only justified in the most exceptional cases where one kidney is proved to be the cause of profound toxæmia and the other kidney is in the earliest stage of tuberculous infection.

### Technique of Nephrectomy

The technique of nephrectomy for renal tuberculois requires no description, but some points call for comment.

#### 1 The Treatment of the Ureter

Many methods of dealing with the tuberculous ureter have been used.

(1) The ureter is cut across below the kidney, the end sealed with the cautery or with pure carbolic acid, and dropped back into the retroperitoneal space. In addition pure carbolic acid is injected into the ureter.

(2) The ureter is cut across below the kidney and the end sutured to the skin in the lumbar wound, or is brought up to the surface inside a drainage tube and fixed there.

(3) The kidney and ureter are removed by the lumbar incision (nephro-ureterectomy).

(4) The kidney is removed by the lumbar incision and the ureter cut across. A second small incision is made in the inguinal region through which the ureter is removed.

A ureter fixed in the lumbar wound retracts and infects the wound with tubercle. The injection of pure carbolic acid is not likely to destroy the tuberculous infection of the ureter and is somewhat dangerous.

In some patients it is possible to remove the ureter through the lumbo-iliac incision, suggested by Morris, but in the majority of cases it is not possible to remove the whole length of the ureter as far as the bladder by this incision. A stump of varying length is left attached to the bladder. The same limitations attend the removal of the ureter through a small incision in the iliac region.

The method that I have practised for many years, and that I have found satisfactory, is to remove the ureter as far as the brim of the pelvis through the lumbar wound, seal it with the cautery or with pure carbolic acid, ligature, and drop it into the retroperitoneal space. The patient is re-examined in six months, and if there is reason to believe that the disease is still active in the ureter and is infecting the bladder, extraperitoneal ureterectomy is performed through a median suprapubic incision. The cases in which ureterectomy is advisable are those where there is stricture at the lower end of the ureter and dilatation of the duct. The proportion of cases in which this is required does not exceed 8 per cent.

#### 2 Closure of the Lumbar Wound

In the majority of cases of nephrectomy for renal tuberculois I close the wound without drainage at the end of the operation. Drainage may be necessary on account of oozing or of infection of the perinephric tissues with tubercle or other bacteria. Where all cases are drained a sinus persists in some, and may take months to heal. Infection from tuberculous deposits in the perinephric fat may be the cause of the sinus, but it is usually due to a mild post-operative staphylococcal infection.

Leguen<sup>7</sup> has shown that tuberculous deposits are found in the perinephric fat, and it is suggested that the fatty layer should be removed with the kidney. This is easy in the early stage of the disease, but impossible in advanced tuberculosis where there are masses of perinephric fat extending under the diaphragm.

It is an occasional experience to find that the wound heals completely by first intention, and a few weeks later one or more weak spots appear in the scar. These are small superficial areas of tuberculous infection, and should be treated by scraping, the application of iodine, and the administration of tuberculin.

Thevenot<sup>8</sup> describes a complete breaking down of the wound from tuberculous infection (*tuberculation totale*), of which he has collected 11 examples. I have seen one case of this nature in which, after the wound had eventually healed, the patient died of general tuberculosis four months after the nephrectomy.

#### Effect of Nephrectomy on Tuberculous Infection of the Bladder

A temporary increase in the bladder symptoms is not uncommon immediately after nephrectomy. Tuberculous cystitis and ulceration gradually subside, and the bladder eventually becomes free from tuberculous infection. We have seen the bladder infection as of comparatively recent date.

bladder symptoms entirely disappear and the full capacity of the organ is restored.

Where tuberculous cystitis has been established for some time the bladder seldom regains its full capacity after the cystitis has disappeared, and a frequency of two hours becomes permanent. Tuberculous cystitis and ulceration may persist for some years when the whole of the renal and ureteral infection has been removed. The urine in such cases may be clear and contain no tubercle bacilli and only microscopic pus.

The treatment of the bladder after nephrectomy for tuberculosis consists in the administration of soothing drugs, such as sandalwood oil, and the administration of tuberculin. Washing of the bladder had better be avoided, for it does not affect the tuberculous process and may cause a mixed infection. I have not seen any permanent benefit from the injection of strong solutions of mercuri perchloride or carbolic acid. Craterization of a tuberculous ulcer with the high frequency cautery (etmellage) has been recommended by Heitz Boyer<sup>1</sup> and others, and is likely to be of assistance when the ulceration is superficial and limited.

#### Operation Mortality

The operation mortality has fallen during the last twenty five years and statistics which include only cases of comparatively recent date have the benefit of more accurate methods of diagnosis, improved technique and the fact that patients are now referred to the surgeon at an earlier stage of the disease than heretofore.

Persson calculated his operation mortality in 205 cases treated during thirty years as 7.3 per cent, whereas the 85 cases operated on in the last five years showed only 4.7 per cent mortality.

The following are some recent series of cases:

	Cases	Mortality
Suter (1923) <sup>2</sup>	204	2.5 per cent
Ferris (1923) <sup>3</sup>	89	6.5
Widdolz (1924) <sup>4</sup>	500	2.4
Hogge (1924) <sup>5</sup>	100	7.0
Gavet (1924)	100	5.0
Judd and Scholl (1924) <sup>6</sup>	683	2.7
Persson (1925) <sup>7</sup>	205	7.3
Condamin (1926) <sup>8</sup>	172	2.9
Young (1926) <sup>9</sup>	112	0.89
Thomson Walker (1927)	193	2.5

#### Late Results

The late mortality of cases of renal tuberculosis where nephrectomy has been performed, if intercurrent disease be disregarded, depends upon tuberculous infection of the second kidney and tuberculous disease elsewhere in the body. Infection of the second kidney may have been present at the time of the operation, or the kidney may be infected later from the original source of the tubercle. When complete investigation of the urine or the second kidney is carried out by animal inoculation the risk of this is very small. It is more likely that infection of the second kidney is derived from the original source at the time or soon after the operation.

The number of cases in which the patient dies of general tuberculosis is considerable. Persson points out that acute military tuberculosis occurs twice as often during the first six months after the operation as in the total of the following years.

Of 193 patients on whom I performed nephrectomy for renal tuberculosis 5 died and 188 recovered. Of the 188 survivors I was able to trace 111 and failed to obtain information in regard to 77.

Of the 111 survivors there are 67 well and without any symptoms of urinary disease at periods varying from 1 to 22 years after the operation (60.3 per cent).

The period that had elapsed since the nephrectomy in these cases was: 1 year in 10, 2 years in 9, 3 years in 4, 4 years in 1, 5 years in 1, 6 years in 7, 7 years in 4, 8 years in 4, 9 years in 3, 10 years in 5, 11 years in 2, 12 years in 4, 13 years in 3, 14 years in 4, 15 years in 4, 16 years in 1, and 22 years in 1.

There were 25 patients (22.5 per cent) who were in good general health but still had bladder symptoms. In some cases the frequent micturition was due to permanent contraction of the bladder without tuberculous disease. In other cases there was persistence of the tuberculous infection. The period of time that had elapsed since operation in these cases was: 1 year in 6, 2 years in 5, 3 years in 1, 4 years in 2, 5 years in 3, 6 years in 1, 7 years in 4, 9 years in 1, 12 years in 1, 20 years in 1.

Thus there were 92 out of 111 cases traced (82.8 per cent) where the patient was in good general health at periods varying from 1 to 22 years after the removal of the tuberculous kidney.

Of these 92 cases 35 had been operated on three years or less from the time of the inquiry and in 57 or 61.9 per cent 4 years or more had elapsed since the operation. Of the 111 cases the remaining 19 cases (17.1 per cent) had died since the operation: 4 from intercurrent disease (2 one year and 2 twelve years after the operation) that had no relation to tuberculous disease and 4 from unknown causes but probably from tuberculous disease in some form (2, 3, 6 and 10 years after the operation). The remaining 11 cases died of tuberculous disease: 6 from general tuberculosis (2 one year, 1 two years, 2 three years, 1 eight years), 2 from tuberculous disease of the second kidney (3 and 7 years) and 3 from tuberculosis of the lungs (2, 4 and 8 years).

Of the 19 patients that died after the operation 11 or 57.8 per cent, died during the first three years. This agrees with the opinion of Israel and of Persson who found that 50 per cent of the late mortality occurred during the first three years after the operation.

The late mortality from tuberculosis disease of the remaining kidney in my cases is small—namely 2 in 19 cases or 10.5 per cent.

General tuberculosis caused death in 6 cases (31.5 per cent) and 5 of these deaths occurred within the first three years. Tuberculosis of the lungs accounted for 3 deaths, 2 of which were in the second and fourth years respectively.

The following are some of the statistics of the late results:

Surgeon	Cases Traced	Dead	Completely Well	Improved but not Completely Well
Persson	182	Per cent 4.7	Per cent 57.1	Per cent 5.8
Suter	197	29.9	41.6	25.3
Judd and Scholl	611	11.0	53.6	10.0
Nitch	43	12.0	2.0	35.0
Wildbolz	—	19.4	61.5	—
Thomson Walker	111	17.1	60.3	22.5

#### Non-operative Methods of Treatment

I have treated a number of cases of renal tuberculosis with tuberculin (Koch's new tuberculin T.R.) without operation. These were cases where the patient refused operation or where the disease was bilateral and operation was contraindicated.

In adults I have seen no case of cure with tuberculin. There was frequently amelioration of the symptoms and improvement of the general health for several years, but the tuberculous disease persisted. In one child with bilateral tuberculosis the symptoms vanished, the general condition steadily improved, and pus and tubercle bacilli disappeared from the urine. In another boy the symptoms improved and the patient gained weight but the tubercle bacilli and pus in the urine persisted and the tuberculous cystitis was unchecked.

In all cases of renal tuberculosis I give a course of two years of tuberculin T.R. after nephrectomy. This has a beneficial effect on the tuberculous infection of the bladder and is given also with the hope that the primary focus of infection in the mediastinal glands or elsewhere will be influenced by it.

#### Sunlight and the Ultra-violet Rays

Tuberculosis of the kidney cannot be cured by exposure of the patient to sunlight. I have seen a number of cases where this form of treatment has been used, but in none of these has there been the semblance of a cure. Cases have been recorded where the pus and tubercle bacilli have disappeared from the urine some years after this treatment. Our knowledge of the pathology of renal tuberculosis shows that temporary occlusion of a tuberculous focus may take place without this treatment but that sooner or later the tuberculous disease progresses and destroys the kidney.

The temporary improvement that may take place from treatment by sunlight unfortunately encourages the patient to resist operation or to postpone it and thus much valuable time is lost.

Heliotherapy is a valuable method of treatment after operation for tuberculosis of the kidney, and it has also a useful field in cases where operation is contraindicated.

In an inquiry among the physicians of Switzerland, Wildbolz found that of 316 patients suffering from renal tuberculosis not operated upon 31.3 per cent died within the first two years of the disease, and 27.2 per cent within three to five years. More than half (58 per cent) died within the first five years, and only 20 per cent were alive after five years.

## STATISTICS OF POST-OPERATIVE SURVIVAL IN RENAL TUBERCULOSIS.

BY

ANDREW FULLERTON, C B, C M G, M D, M Ch,  
P R C S IREL,

Professor of Surgery, Queen's University, Belfast

WHEN a patient is brought to the surgeon for renal tuberculosis two questions obtrude themselves (1) Is the lesion confined to one kidney? and (2) Is cure without operation possible?

Recently I set out to investigate a series of 158 cases of tuberculosis of the bladder seen over a period of twenty years. It was found to be very difficult to trace these cases, but some useful information was obtained. One of the objects of the investigation was to compare the results of operation, when the kidney was affected, with those obtained by other measures, among which the most important and the most popular was the use of tuberculin.

Of the 158 cases there was definite evidence of kidney involvement in 141. In the remainder evidence was wanting—either on account of the difficulties associated with ureteral catheterization, or because, in the early days, it was assumed, probably without sufficient justification, that the bladder condition was secondary to involvement of the epididymis, prostate, or vesiculae. Further observation has shown that tuberculosis of the sexual organs frequently coexists with or follows renal tuberculosis. Thus there were 87 males in the series, and in no fewer than 29—that is, in one-third—there were deposits of tubercle in the prostate, epididymis, or vesiculae. In only 7 out of the 141 cases was there definite evidence, at the time of my examination, of a bilateral lesion—that is, in about 5 per cent.

In all cases an attempt was made to find a primary focus. A previous history of some tuberculous lesion was obtained in 26 per cent, and in 15 per cent a focus was found at the time of examination in some part of the body outside the genito-urinary tract. In many cases, no doubt, hidden foci were present in glands, bones, etc., but they were not sufficiently obvious to arrest attention during an

ordinary clinical examination. This leads me to say that I have frequently been struck with the apparently robust health which many patients the subject of urinary tuberculosis enjoy. Many go on for years with much inconvenience and suffering before the general health becomes seriously impaired.

As opposed to the views I have long held regarding the localization of the infection to one kidney, and the prospects of cure without operation, a recent paper by Gilbert J. Thomas and Thomas J. Kinsella<sup>1</sup> is very interesting, and instructive. These authors have conducted a research in a well equipped sanatorium in Minnesota for the treatment of tuberculosis. Their conclusions include the following:

They argue that tissue destruction with renal tuberculosis is a late lesion, and that this is the lesion most frequently seen by the surgeon. They bring evidence to prove that early renal tuberculosis may end in arrest or cure. They believe that tubercle bacilli are carried to the kidney by the blood stream, and that every renal infection with tubercle bacilli must be primarily bilateral. One kidney may not overcome the infection so well as its mate, and a destructive lesion develops. They have never been able to demonstrate a case of excretory bacilluria. They have never removed a kidney which eliminated tubercle bacilli that did not contain a lesion of tuberculosis, though in some instances serial sections were necessary before the lesions could be found. Repeated urological examinations revealed many cases of unsuspected renal tuberculosis among their patients, nine-tenths of whom had active pulmonary lesions.

I have had very little opportunity of examining patients representing this class of case. Those who have been referred to me have had what these authors term "tissue destruction," and in the large majority, as I have stated, I have been unable to find evidence of bilateral infection. It is quite true, of course, that the absence of pus and tubercle bacilli in the specimen obtained by ureteral catheter from a kidney is not conclusive proof of its freedom from disease. Foci may be present in the cortex, for instance, and may not communicate with the pelvis, or an abscess in the pyramis may be shut off, only discharging into the pelvis at intervals, but the difference between the urines excreted by the diseased kidney and by the presumably sound kidney has been, in my experience, so definite and decided in almost every case examined that I cannot come to any other conclusion than that the disease is unilateral, clinically, at any rate, in the cases coming under my observation. The specimen obtained from the affected side, besides containing pus and tubercle bacilli, is, in nearly 100 per cent of the cases, of a low specific gravity. In the early cases the low specific gravity is associated with an increased flow, which may be termed unilateral diuresis. In the later stages the urine, though still of low specific gravity, may become diminished in quantity, until finally no fluid at all is secreted, and the discharge from the kidney may be represented by a cement solid ointment-like material, or the ureter may become impenetrable, and all connection between the affected kidney and the bladder cut off. The low specific gravity in the late cases is due to renal insufficiency, a condition which it may be possible, by chemical analysis, to distinguish from the hyperactivity seen in the early stages.

I have been able to demonstrate by repeated ureteral catheterization in cases of renal calculus that pure reflex unilateral diuresis occurs, with low specific gravity, and dilution of the specimen from the affected side, and that, on removal of the cause, the rate of flow, the specific gravity, and the composition of the urine rapidly return to normal, and become identical on the two sides.

A similar diuresis occurs in the early stages of tuberculosis, and appears to be due to reflex vaso-dilatation, in contradistinction to the vaso-constriction which gives rise to reflex anuria—a condition well known to occur in certain cases of calculus.

My colleague Dr. Mayrs of Queen's University, Belfast, has recently made analyses of the urines of 35 patients under my care with various unilateral kidney diseases. These analyses have been carried out in order to ascertain whether ureteral catheterization can throw any light on

\* A contribution to a discussion on renal tuberculosis in the Section of Surgery at the Annual Meeting of the British Medical Association, Edinburgh, 1927.

the nature or extent of the renal impairment. Reflex diuresis must be distinguished from renal insufficiency, as in many cases diuresis results from increased rate of excretion alone, and it is in trying to recognize the distinctive characteristics of these two conditions that the fundamental difficulty is encountered. Owing to possible leakage past the catheters the volumes of urine from the two kidneys cannot always be compared with sufficient confidence to justify a positive diagnosis of unilateral diuresis, while, even if the occurrence of diuresis has been satisfactorily established, more serious impairment of function is not excluded.

A method of attacking the problem is to compare the concentration of various substances (chloride, urea, phosphate, creatinine) in the urines secreted simultaneously by the two kidneys. But although this has been done in numerous cases, the results fail to give all the information required, because we are not quite sure what alteration in the ratio of creatinine to urea, for example, should normally result from an increase in the rate of flow, when this is the only variable factor. At the same time, a careful study of such changes is not without value. Probably chloride excretion will afford the most reliable distinction between diuresis and insufficiency, but a good deal of work remains to be done. It is a general principle that in diuresis the composition of the urine approaches more nearly to that of the plasma and hence, if the diuresis is unilateral, the chloride concentration of the urine on the affected side should be closer to 0.6 per cent NaCl than that from the normal kidney. An increase or decrease of chloride concentration may thus result, which can be interpreted by comparison with the chloride content of the normal urine, the latter being above or below 0.6 per cent according to whether the excess of chloride in the organism is large or small. On the other hand in renal insufficiency the chloride of the urine is always low, and often considerably lower than that of the plasma.

The object of these remarks on low specific gravity is to stimulate research, so that it may, perhaps, be possible from an examination of the specimens from both kidneys, to state what degree of disorganization has taken place in a kidney affected with tuberculosis, should the surgeon be tempted to give a trial to non-operative methods of treatment.

There is another point to which I would like to direct special attention and that is the fallacies and difficulties associated with ureteral catheterization. The introduction of a ureteral catheter may upset the sphincteric mechanism of the ureteral orifice and may thereby give rise to erroneous conclusions and in addition, may entail some risk of infection of the sound kidney.

A girl aged 23 years was ex-cooped and catheters were introduced into both ureters. A small number of pus cells were found on the right or presumably sound side. The examination was repeated and the bladder was emptied during the collection of the ureteral specimens. That on the right was scanty in quantity, clear amber in colour, had a specific gravity of 1010 and was free from pus. That on the left was copious, pale and cloudy, had a specific gravity of 1005 and contained many pus cells. Fluid was now introduced into the bladder through the cystoscope. After a few ounces had been injected the patient began to complain of pain on the sound side and immediately a quantity of watery fluid appeared as a distinct layer supernatant to the amber fluid previously obtained. The fluid in the bladder had evidently reached the pelvis of the kidney past the ureteral catheter and had found its way out again through the lumen of the latter into the collecting test tube. On removing the fluid from the bladder clear amber urine was again obtained from the ureter of the sound side.

The significance of this from the point of view of diagnosis and of possible infection of the sound kidney by ureteral catheterization is obvious. I make it a rule now to empty the bladder before commencing to collect the ureteral specimens.

Again in a certain proportion of cases it is impossible to catheterize the ureters. This is due to extensive ulceration and great irritability of the bladder. Attempts to persist in cystoscopy may cause much bleeding and straining and are not devoid of risk. It is for these cases that I have suggested and carried out retroperitoneal catheterization of the ureters by open operation.<sup>2</sup> The ureter may be exposed by stripping inwards the peritoneum

after an incision in the parietes similar to that used for appendicectomy. In tuberculosis of the kidney if a thickened ureter be found on one side it ought not to be disturbed, as the small puncture made to receive the ureteral catheter may not heal and may persist indefinitely as a fistula. On the sound side with careful technique and accurate suturing there need be no extravasation of urine.

Instead of introducing a catheter the needle of a small exploring syringe may be used and the wall of the ureter punctured just as is done in withdrawing blood from a vein. To facilitate collection of the specimen, the distal part of the ureter may be lightly clamped so as to allow urine to collect in the proximal portion. This procedure should eliminate all risk of leakage, especially if the puncture be made obliquely through the wall of the ureter. By operative ureteral catheterization the exact amount of urine secreted by a kidney can be ascertained. The specimens so obtained are free from the risk of contamination by reflux of the bladder contents, and the operation is safer than sustained attempts to distend an ulcerated bladder.

I have used this method when after careful search, the opening of the ureter in the bladder could not be found and in one such case—a case of tuberculosis of the kidney—no ureter could be discovered on the opposite side, even after operative exposure of its normal position in the iliac region. This patient had only one kidney, which was tuberculous. In several other cases I have found a thickened and impervious ureter demonstrating the final stage of the process of auto-nephrectomy, which is responsible for many of the so-called cures without operation.

#### TECHNIQUE

In my most successful cases I have removed the kidney and as much of the ureter as I could reach through the lumbar wound. I have made no elaborate attempt to dissect out completely the perirenal fat. I have not found it necessary or desirable to dissect out the ureter. Indeed I have only done this in two cases and one of my worst results was in a case so treated. Some months after the operation urine began to leak from the stump of the ureter at its junction with the bladder, into the wound, which after having healed by first intention had opened up. This patient died seven and a half months after operation from uræmia following an operation by another surgeon to repair this leak. The removal of infected glands surrounding the pedicle of the kidney close to the spine is attended with risk. A large blood vessel such as the renal vein or the vena cava may be injured. I do not say that these glands ought not to be removed if possible but I have often left them untouched when clearly bound down in an inaccessible position without any obvious disadvantage to the patient.

As a rule the wound in the parietes has been sutured without drainage. In a few cases a drain was left in for twenty-four hours. In some cases the wound broke down at one or more points a month or more after operation, after having healed by first intention. Final healing was the rule after the sinus or sinuses had lasted for periods varying from a few months to a year or more.

I have tried all the recognized methods of dealing with the ureter at the point of section. My present practice is to inject with a hypodermic syringe pure carbolic acid into the lumen over an area of an inch or more before ligaturing and dividing the ureter. Catgut has been used in all cases for securing the pedicle and for the deep sutures, and silkworm gut for the skin.

#### STATISTICS

Nephrectomy was carried out in 73 out of the 141 cases of renal tuberculosis. Five died as the result of operation—a mortality of 6.8 per cent. All the deaths occurred in the first 35 cases, the remaining 38 being without operative mortality. I have been able to follow up 55 out of the 63 survivors. Fifteen have since died, four of them after long periods of complete relief. Thus one died, 12 years after operation from what was called a "cerebral attack", one 9 years after, from cerebral hæmorrhage, one 8 years after, from acute pneumonia, and one 9½ years

after, from gangrenous cystitis, probably non-tuberculous. All the cases enjoyed good urinary health in the intervals. This leaves 11 cases dying as the result, probably, of a continuance of their tuberculous infection. Thirty-one of the survivors are described as being well—on 20 years after operation, two 17 years after, one 16 years after, one 15 years, one 14 years, one 11 years, one 9 years, one 8 years, two 7 years, three 6 years, one  $5\frac{1}{2}$  years, one 5 years, three 4 years, one  $3\frac{1}{2}$  years, two 3 years, two  $2\frac{1}{2}$  years, four 2 years, and three cases from 6 months to 1 year after operation. Including the four patients who died from other causes, eight years or more after operation, we have a total of 35 out of 55 apparently cured of their urinary symptoms—that is, over 63 per cent. Of the nine survivors who cannot be claimed as cures, one still has frequency and wears a urinal, though otherwise in good health, 12 years after operation. One has frequency 7 years after operation—his lungs are now said to be affected, one is said to be fairly well 5 years after operation, but he now has deposits in his epididymis, and is said to be suffering from spinal caries, one has still frequency and wears a urinal  $6\frac{1}{2}$  years after operation, one still has frequency 2 years after operation, and deposits have appeared in epididymis and prostate, one still has frequency 2 years after operation, one still has frequency 1 year after operation, one is much improved, but not quite well, 1 year after operation, and one is much improved, with apparently normal urine, 4 months after operation.

Contrast with these the reports received of those treated by medical means, of which tuberculin was the one most frequently used. I have only been able to trace 41 out of the 68 cases not subjected to operation. These were of the usual type, and (except in 5 or 6 advanced cases) operation was not contraindicated when the patients were first seen. Of the total, 26 are dead—that is, 63 per cent. One lived for 17 or 18 years after the onset of symptoms, and died after the removal of a calculus, which had blocked the ureter of the affected kidney, and mushroomed into the bladder. One lived for 16 years. Fourteen died in from 2 to 6 years, three in from 1 to 2 years, and seven within a year after the onset of symptoms. Of the fifteen living, one is certainly well 13 or 14 years after the onset of symptoms, the urine is free from pus and tubercle bacilli, the condition of the affected kidney has not been ascertained. Another is well and free from urinary symptoms 5 years after they first appeared. The ureter of the affected kidney was exposed, and was found to be converted into a thick fibrous cord. There was no trace to be seen of its orifice on cystoscopic examination. These are the only ones, two in number, that I know of, who are really well. Of the remainder, one has carried on fairly well, with symptoms, for 16 years, another similarly for 15 years, and a third for 13 years. In none of these three cases was ureteral catheterization carried out. Deposits were present when first seen in prostate, vesiculae, or epididymis, and in all three tubercle bacilli were found in the urine. The diagnosis of kidney involvement was made by cystoscopic examination of the ureteral orifices. One early bilateral case is reported to be well except for an occasional "turn" of frequency,  $7\frac{1}{2}$  years after the onset of symptoms. Lastly, in the other survivors, symptoms remain 5 years and under from the onset of their illness.

These statistics support the contention that, with our present knowledge, operation remains the most hopeful method of treatment in tuberculosis of the kidney. If done early, before deep ulceration has taken place in the bladder, relief is often immediate. Even in late cases, if the other kidney is sound, the patient may still be cured. Deep ulceration of the bladder, and the presence of tubercles in that organ—a late occurrence in my experience—render the prognosis less hopeful, especially as regards the relief of frequency of micturition. Even if healing takes place, the scarred and contracted bladder is unable to expand, and the patient is obliged to empty it at frequent intervals.

## DISCUSSION

Dr A. ROLLIER (Leysin) thought that heliotherapy could play only a subsidiary part in the treatment of renal tuberculosis. In every case of unilateral disease he advised nephrectomy as soon as the diagnosis was established, but heliotherapy was indicated as a pre-operative treatment for patients whose condition was bad, since it improved the general and tissue resistance, thus helping to prevent tuberculous infection of the wound. It was also useful in all cases of unilateral disease when the cystoscopic and functional examinations left any doubt about the integrity of the other kidney. Heliotherapy could be employed with benefit when the seminal glands, and particularly the prostate, were the seat of extensive disease which compelled the postponement of cystoscopy owing to the risk of trauma of the prostate, with the consequent danger of general infection. As a post-operative treatment it helped to prevent the infection of the wound, and assisted cicatrization of infected wounds. In bilateral renal tuberculosis heliotherapy was the treatment of choice, since it limited the extension of the lesion and diminished the pain of bladder ulceration. To be efficacious heliotherapy must be conducted with rigorous technique and special adaptation to the needs of the patient. It should be associated as often as possible with graduated labour.

Mr HENRY WADE (Edinburgh) described a series of seventy-eight cases in which he had operated. He thought that the diagnosis could be made independently of the demonstration of the presence of tubercle bacilli in the urine, and that frequently an x-ray examination would clear up the diagnosis by revealing calcification. Pyuria without organisms in the urine and diminution of the bladder capacity were very characteristic. On cystoscopy the "golf-hole ureter" was diagnostic. He performed a bilateral catheterization and a bilateral pyelography. The pyelogram might show the drainage system of one part of the kidney to be normal and the other part excavated, irregular contractions and dilatations of the ureter were pathognomonic of tuberculosis. He had never obtained spontaneous clinical cure nor post-mortem evidence of healing, and therefore regarded nephrectomy as the correct treatment. Two of his seventy-eight patients had died. After an operation the ulcers in the bladder usually disappeared. If there was any frequency left, it was due usually to the small size of the bladder. The frequency and inability to dilate were sometimes due to a single remaining ulcer, the excision of which would bring about a rapid cure. A superadded streptococcal infection was very difficult to eradicate.

Mr J. F. DOBSON (Leeds) referred to cases where it was impossible to tell by cystoscopy whether the disease was unilateral or bilateral, and catheterization by the ureters was impossible. Opening the bladder suprapubically would not help in the difficulty, but Mr Fullerton's method of exposure of the ureters in the iliac regions was of immense assistance. Mr Dobson said that he had modified the method, he exposed the ureters and found that it was possible to tell from their appearance, state of dilatation, peristalsis, and feel of the walls whether the corresponding kidney was diseased or healthy. It was unnecessary to open the lumen of the ureter. He had used the procedure with satisfaction in four cases of advanced disease when cystoscopy was unable to furnish the required information.

Mr BERNARD WARD (Birmingham) based his remarks on a series of 57 cases. He believed that tuberculous infection started in the papillae, and that the upper papillae were affected more often than those in the lower part of the kidney. No operation should be undertaken unless the disease was limited to one kidney. A diseased kidney often secreted a large quantity of urine, and its removal threw a greater strain on the remaining organ which accelerated any disease present in it. The only certain method of diagnosis was to draw off urine from the infected kidney by the catheter. His custom was to estimate the combined renal function by means of the urica concentration.

and blood urea test, with chromocystoscopy, using indigo-carmin injection, and to catheterize the ureteric openings. The last method was sometimes sufficient in itself by revealing the presence of pus cells in the collected specimen. He had found spinal anaesthesia a great help in performing cystoscopy, it did not interfere with renal function and gave greater relaxation of the inflamed bladder than the deepest general anaesthesia. He refused to operate upon patients with active disease elsewhere in the body whether in the lungs, bones, or joints, mild infection of the genital tract however was not a bar to operation. He rejected as much as he could of the ureter at the primary operation, since he had found that high division of the ureter often left a tuberculous fistula. In one case a pronephrosis was removed unopened, but the whole wound broke down and took two years to heal. He thought infection had come from the perinephric tissues. If frequency remained after six months the patient was cystoscoped and any chronic ulcers treated by operation. In only 37 of his 57 cases of renal tuberculosis had nephrectomy been performed, with one death from military tuberculosis a few weeks later. He had traced 30 of these operation cases and found that 4 patients had since died. Of the remaining 26 20 were apparently quite well and earning their own living, 6 were unable to earn their living, and one of these developed spinal caries and a poor success but was now getting about. Of the 26 patients still alive one was operated on 15 years ago, one 12 years, one 11 years, two 8 years, three 5 years, five 4 years, five 3 years, and eight were operated on 2 years to 18 months ago.

Mr TEMPLE MURSELL (Johannesburg) emphasized the importance of a thorough investigation of all cases of pyuria, as otherwise cases of tuberculous kidney would be overlooked until they had become advanced. He had never seen a patient cured without operation though improvement sometimes occurred and persisted for as long as ten years. Early nephrectomy, followed by heliotherapy, gave the best results. He did not remove the whole ureter. Tuberculin was of great value in reducing residual bladder symptoms.

Mr GONNOR CRAIG (Sydney) had seen two cases of renal tuberculosis cured without operation. One patient had bilateral disease and a tuberculous fungus the latter was treated surgically. Tuberculin was administered and now, fifteen years later, cystoscopy of the patient revealed no signs of disease. He recommended epidural anaesthesia for cystoscopy.

Sir JOHN THOMSON-WALKER, in reply, said that he could not agree with Mr Dobson that it was possible to deduce the state of the kidney from inspection of the ureter. Nor did he agree with Mr Wade's method of diagnosis by pyelography. He said that clinical cures of tuberculosis of the kidney were always suspect pathological recovery was very rare indeed. Indigo-carmin injection was unreliable as a test for kidney function. The removal of the perinephric fat in advanced cases was impossible and removal of much of the ureter was unnecessary. He did not recommend phenol injection of the ureteric stump, for the drug did not reach the thickness of the wall where the infection lurked.

## DUTIES OF THE STATE IN RELATION TO THE NATION'S FOOD SUPPLY

### RESEARCH ON NUTRITIONAL PROBLEMS \*

BY

EDWARD MELLANBY, M.D. CAMBR. F.R.S.

Professor of Pharmacology, University of Sheffield, Honorary Physician, Sheffield Royal Infirmary.

SOME of those interested in this discussion must have wondered what exactly the officers of this Section of Preventive Medicine had in their minds when they used the words 'What duties has the State?' Did they mean by "duties" obligations imposed in the present time by Act of Parliament? If so, the discussion resolves itself more or less into a recital of those official activities which bear on the subject of nutrition and feeding. It must be assumed that this is not wanted, but rather the consideration of the problem as to what an ideal State should do in regard to carrying out research in nutritional matters, in the instruction of parents in maintaining food supplies, and providing cooking facilities.

In the first place it may be worth while to consider whether feeding problems are a profitable field for Government activity. Nobody would deny that State and local government interference in matters of health especially as it is affected by sanitation and drainage, water supply and limitation of spread of infectious disease has been of untold benefit to the community. Is it likely that a similar interest in feeding will be followed by beneficial results of a commensurate order? Some may think not but for myself, and speaking probably for all those in touch with modern work on nutrition, I should say that the outcome of a sane and forceful effort on the part of imperial and local governing bodies in this field would lead to as revolutionary a change in the general health of the community as has followed their work on matters of public hygiene.

In a sense the problem of correct feeding is even of a more fundamental nature than that of general hygiene, for whereas it is possible to bring about good health and perfect

development under bad hygienic conditions so long as the food eaten is very good, when the diet is defective the most perfect hygiene as we know it will not prevent had physical development ill health, and early death. Good hygienic conditions may for the moment be described as those conditions which reduce the chance of infection by micro-organisms, but nothing has been more prominent in recent work on feeding problems than the part played by correct feeding in increasing the individual resistance to infection. It is true that our knowledge of this problem is of an elementary nature but the subject is one of active interest at the moment and further facts of great importance will no doubt come to light very soon. I need only allude to the recent accumulation of facts showing the importance of vitamin A in increasing the resistance of the animal to inflammatory conditions of the respiratory passages and lungs as a forerunner of knowledge on the relationship between diet and resistance to infection. But apart from this large question of the relation of feeding to infection there remain the purely metabolic disorders which are brought about by incorrect diet among these may be instanced the bone deformities and the defective dental structure and growth of jaws which follow deficient vitamin D intake, the symptoms of scurvy due to deficient vitamin C the nervous symptoms due to deficient vitamin B the goitre due to deficient intake of iodine the stunted growth due to deficient intake of biologically good protein, and the ill effects of excessive and unbalanced cereals. These are some of the more recently established facts and, even if they are not greatly extended in the near future, they are sufficiently important in themselves to justify the belief that it is certainly a most profitable line along which the activities of the State should be directed and hastened. The question now arises as to the methods to be adopted for the acquisition and diffusion of new facts concerning nutrition, and the relation of these facts to the public weal.

With regard to research on nutritional problems, the machinery, or at least the skeleton of the machinery, is present in the Medical Research Council. Since this body was set up a large part of its activities have been directed to the solution of nutritional problems. It was a most happy occurrence for the progress of nutritional studies that the Medical Research Committee was appointed soon after the enunciation of the vitamin problem, and that

\* A paper read in the Section of Preventive Medicine at the Annual Meeting of the British Medical Association at Edinburgh in introducing a discussion entitled 'What duties has the State in relation to the nation's food supply?' regarding research in nutrition of parents, maintenance of supplies and cooking facilities.

Sir Frederick Gowland Hopkins, one of the original and present members, should have played the leading part in this work. It is true that at that time nobody could foresee what an extraordinary part the vitamins were playing in the production of disease common in this country, but at least the field was set and all the circumstances were propitious for the rapid accumulation of facts which followed.

The Medical Research Council has always been ready to support work on nutritional problems to the limit of its meagre resources. Unfortunately its limited income is not the only drawback to rapid progress in this part of its work, for the field of workers upon which it can draw is very small. Work of this type does not attract young men, and even those who have found themselves in this field have often arrived there by accident. There are many reasons for the lack of popularity of this kind of investigation, but probably the greatest of these is the spirit of scepticism and even hostility which has surrounded the subject of feeding, especially as it concerns vitamins. Many of the established physiologists and pathologists of this country have not only failed to see the scientific and practical significance of the new dietetics, but have been sceptical and often even hostile as to the existence of these substances. The popularity of the subject among the general population and the uncritical way in which vitamins have been discussed have only made the atmosphere which surrounds nutritional investigation worse.

It is possible to foresee the end of this period of unpopularity, as even the scientist with the longest latent period cannot fail to be aroused by recent work on the intracellular vitamin and its photosynthetic production by the action of ultra-violet radiations on ergosterol. These recently discovered facts must tend also to focus the attention on particular problems and prevent the loose thinking and talking that is so widespread in matters dietetic. The facilities for nutritional investigation, or at least financial facilities, have been recently greatly extended by the formation of the Empire Marketing Board. The liaison between this body and the Medical Research Council is to be highly commended, and it is to be hoped that attention will not only be given to technical problems connected with storage and transmission of food, but that an eye will be given to the more academic problems of diet which form the fundamental basis for all future advances in knowledge as to the relation of feeding and health.

Interwoven with the advances in knowledge of nutrition is the problem of animal feeding, attention to which is being given by the Board of Agriculture, whose financial resources as compared with those of the Medical Research Council are very great. Speaking as one whose time has been largely occupied in investigating problems which are certainly as important from an agricultural as from the human aspect, I have a strong feeling that the inter-relationship between nutritional research as carried on in the university laboratories of this country not primarily devoted to agriculture and that of the Board of Agriculture is not so close as it ought to be.

On the whole, so far as matters of research in nutritional problems are concerned, it is probably safe to say that the official machinery of this country is well established and likely to grow from strength to strength. Care must be taken that, as it grows, co-ordination of the work grows with it, so that not only should there be a rapid diffusion of new facts as they come to light and a limitation of unnecessary overlapping, but, what is of supreme importance, individual workers should be able to take up quickly the newer and often better point of view as it becomes established. Better co-ordination and more intimate knowledge of each other's work would not only result in more rapid progress, but would greatly reduce the hostility, too often encountered, where one group of workers denies the results of another group. The antagonism to Lister's teaching of antiseptics is only one instance of what is far too common in this country.

So far as the acquisition of new facts on nutritional matters is concerned, things are, on the whole, well, but what about the mechanism for the dissemination of this knowledge and for making full use of it? Here again the mechanism is at hand in the form of the Ministry of

Health and the Board of Education. The first of these bodies has its nutritional advisers among its officers, and in recent years has undertaken a large number of tasks which involve advice in feeding and the dissemination of knowledge of dietetics. I need only mention the establishment by local health authorities of maternity and child welfare centres. The Ministry of Health also has its Research Department, whose activities are, however, more concerned with the investigation of technical points concerning foodstuffs than with the acquisition of more fundamental facts.

It is evident that the State has some machinery for directing the dissemination of knowledge of nutrition as it is required, and the question must now be faced as to whether this mechanism is satisfactory, and, if not, how it can be improved. It is an easy matter for an outsider to criticize and suggest improvements, but before venturing to do so I should like to pay tribute to the excellent work now being carried out by the Ministry of Health and educational authorities along these lines. Nobody has a greater admiration for the civil servant of this country than I have, and this admiration extends as much to the Ministry of Health as to other governing bodies. At the same time it is perfectly certain that knowledge of dietetics is greatly in advance of the application of this knowledge and the adoption of its teachings by official authorities. The reason for this is easily understood. Government officials must play for safety, and the greatest crime in their eyes is to make a statement one day which has to be retracted at a later period. However valuable their teaching might be in other respects, a mistake is unforgivable, so that their advice must be limited to what is considered as generally accepted. This means a latent period of many years as regards most discoveries. Their task is not lessened, so far as dietetics is concerned, by the multitudinous teachings of experts and so-called experts. What, for instance, is an official to do when faced with the many suggestions as to the dietetic means of saving the rice which fill our daily papers? These suggestions are not only multitudinous but are often contradictory. They represent the views of a few who know, more who half know, and many who are entirely ignorant of the subject. The average intelligent reader smiles and rejects the lot.

Nothing is more clear than that any system must be inefficient which leaves discussion as to active policy in matters of dietetics to one or more officials whose time is largely taken up with administrative work. How to improve the situation is difficult to suggest. One obvious and essential method would be to appoint a Board of Nutrition to make recommendations to the executive officers of the Ministry of Health. This Board should consist largely of active workers on nutrition with experience of both animal experiments and the feeding of human beings. They should be chosen on the basis of their work only, and no question of representation of learned societies or of particular parts of the kingdom ought to receive consideration. It should be the duty of those members not only to sift the evidence as they read it, but to keep in touch with all those actively engaged on nutritional investigations. Speaking as a laboratory worker I am sure that a good welcome will be given to any official body whose object it is to find out the latest trend of experimental results. As it is, practically the only officials concerned with nutrition who ever visit my laboratory are those from other countries than my own, and I expect my colleagues engaged in this type of work have the same experience. In their active experimental work many investigators are years ahead of their publications, and I consider the direct personal contact with research in progress is a most important function of any official body engaged in advising a Government department. It is at least as important, to my mind, that the Ministry of Health should have a strong and representative body of nutritional experts as it is for the Treasury to have its financial experts, or for the War Office to have its Army Council.

Assuming that we had an efficient method of acquiring new knowledge on nutritional matters, and one by which the Ministry of Health received the best and the latest

advice as to the relative importance of new discoveries, the question now arises as to how such information should be dealt with so that the average citizen could profit thereby. For some people an official announcement of the facts is sufficient, especially if the pronouncement is given with adequate authority. What a boon it would be at the present time, for instance, if out of all the multitudinous teachings presented to us as regards feeding a really authoritative body issued a reasoned statement declaring the relative importance of all the points raised. While such a statement would influence many people, we must not delude ourselves into thinking that it would convince any large section of the population. I can speak with feeling on this point. It is now five years or more since I published the fact that cereals, and especially oatmeal, will, in the absence of sufficient vitamin D, interfere most potently with calcification processes and the general health, but those who realize this are very few in number, in spite of the fact that the evidence is open to anybody to examine. Prejudice and ignorance—both absolute ignorance and ignorance of the value of the scientific method—can only be overcome by time.

Another method by which the Ministry of Health could, if given the necessary authority, greatly increase its effectiveness would be to assume greater control over the feeding arrangements in all institutions run by State and I refer particularly to Poor Law institutions, prisons, welfare centres and similar bodies. Sometimes the sole controlling factor in the minds of the governing bodies is the question of cost of the food although this is by no means always the case. I do not think any local authority need fear a great increase in cost if the feeding were controlled by a wise body of experts representing the Ministry of Health. At the same time I am convinced that the results or the improved health and physique which would follow the adoption of the latest facts of nutritional science would amply repay both any possible increase in cost and any interference of the central dietetic authority.

I can imagine many medical men being alarmed at the suggestion that the Ministry of Health should advise in the feeding of children at welfare centres, but I am sure from my own observations that this would be highly efficacious in many cases—again not in all, for medical attendants at welfare centres are often very alert to new facts regarding nutrition, sometimes even too alert and uncritical, especially where patent foods are concerned.

One other suggestion can be made which would greatly facilitate the working of an authoritative body dealing with nutrition. I refer to the necessity of some scheme for standardizing foods and other preparations for their vitamin content. I am aware that this has recently been boldly tackled—much to their credit—by the Pharmaceutical Society of Great Britain in their new standardizing laboratories. This attempt should be officially encouraged to the utmost extent, and if the methods which are developed prove satisfactory, it should be as much the duty of the Ministry of Health to adopt these by legislation as it is their present duty to test foods for their purity. It ought to be impossible in the near future for people to put on the market preparations about which claims as to their vitamin content are made unless these have been officially tested.

To sum up, I suggest that the following steps should be taken by the State in order to strengthen the control and executive power of the Ministry of Health in matters of nutrition:

- 1 That the Ministry of Health should set up a Board of Nutrition consisting largely of experts actively engaged in nutritional research, whose main duties would be (a) to examine the results of the investigations carried out by those researching for the Medical Research Council the Board of Agriculture the Empire Marketing Board, and all others engaged in this field, both by studying their published work and as far as possible by personal contact with the actual investigations, (b) to advise the Ministry of Health to take action along lines which appeared to them advisable, (c) to recommend, or even to initiate,

research on practical points where there is any obvious hiatus of evidence.

- 2 That the necessary authority be given to the Ministry of Health, acting on the recommendation of its Board of Nutrition, (a) to control the feeding of Poor Law institutions and prisons, and to advise in others, such as welfare centres or wherever public grants are made, (b) to publish authoritative statements, and, if necessary, give the evidence for such, on feeding matters to the general public (c) to set up or control a food analysis department which includes not only the testing of food as at present carried out, but the standardizing of foods and other preparations for their vitamin content.

None of these suggestions is revolutionary and there are only developments of practices at present in use. They would raise the status of nutritional matters to a level compatible with its importance to the nation. They would hasten the adoption of the teachings of dietetics discovered during the past twenty years. They would lead to untold benefits to the health of the community.

#### *The Instruction of Parents*

This I imagine would be part of the duties of the Ministry of Health acting on the advice of its Board of Nutrition. It is probable that official statements made to the press would be the most important method of teaching the facts to the average parent. At the present time this work is being attempted by several well meaning health societies whose members have a strong conviction that diet is a very important subject, but whose knowledge of the facts is often lamentable. These societies would no doubt continue their well intentioned efforts, but their knowledge of the subject would be greatly enhanced and their teachings correspondingly influenced by the official statements of the Ministry of Health. All the numerous public lectures on diet at present given throughout the country would be similarly influenced. The teachings would be unified and the wheat of the subject separated from the chaff. The present method which seems to be growing in popularity of issuing manifestos, to the press on dietetic subjects is altogether wrong. These statements are often partial in their origin and are frequently signed by men who however distinguished they may be in their own lines, cannot possibly have any real knowledge of dietetics. The Board of Nutrition must supersede these well meaning efforts by better method.

#### *Maintenance of Supplies*

If by this is meant the maintenance of sufficient food in the country to supply the necessary amount of energy and protein for each individual in a position to buy it, then it would not appear desirable for the State to take any action except in times of national emergency, as in war especially war accompanied by blockade. On the other hand if it means the maintenance and increased facilities for obtaining special foods and the limitation of others, it is probably a line of action that may prove useful.

The trend of scientific work on nutrition is to divide foods roughly from the point of view of disease into three classes (1) protective or disease-preventing foods, (2) harmful or disease-producing or probably better, "protection-demanding" foods and (3) neutral foods. Among the first or protective foods, would be placed milk, eggs, green and other vegetables fruit cheese meat and fat fish. In the second or disease-producing foods are cereals and cereal products including bread of all kinds (white flour or wholemeal flour) maize oatmeal rice, etc. The third or neutral group of foods, would probably include sugar pulses (peas and beans) pork and bacon and white fish. These are tentatively arranged and it might be desirable with further knowledge to redistribute the members of group (3) among groups (1) and (2). For instance the war in which sugar seems to upset experimentally red dogs suggests that under some conditions it is a harmful food, and if there were any lack of vitamin B in the diet pulses would then pass into group (1) among the protective foods. It may be necessary to point out that the inclusion of cereals and cereal products among the

harmful foods does not mean that these substances are devoid of nutritional properties. They have many excellent qualities in this respect, and their harmful effects can be readily antagonized by some of the members of group (1), or protective foods. At the present time, however, a sufficiency of "protective" foods is often not eaten, and poor physical development and bad health result in many individuals.

In view of these facts it would be desirable for our hypothetical Board of Nutrition to consider whether it was necessary for the Ministry of Health to take steps to make the "protective" foods—milk, cheese, butter, eggs, fat, fish, etc.—more easily procurable by increasing the supplies. It would probably be undesirable at the present time to limit the quantities of the "harmful" group—that is, cereals—available, for these are the cheapest procurable foods and form the basis of the average diet in the country, and especially in view of the fact, as stated above, that they can be made innocuous.

In one other respect—namely, the maintenance of pure food, both as regards micro-organism contamination and admixture with chemicals as preservatives—the State is already active. All of us commend this work and would like to see it strengthened, especially as regards the supply of pure milk. The widespread sale of milk contaminated with tubercle bacilli is a moral and economic disgrace to the country. I think it is time the community faced the probability that the sale of milk bacteriologically clean will be an uneconomic proposition, and it only remains to be determined whether the improvement in health and physique accompanied by some monetary loss is more desirable than widespread tuberculous infection and large monetary profit. A time may come when knowledge of the factors controlling resistance to infection will be sufficiently definite to make it a matter of indifference whether milk is infected with tubercle bacilli or not. Or it may be that an adequate substitute for milk, cheaper and more easily controlled, will be discovered. This time, however, is not yet, and it is important that one of the best "protective" foods in the dietary should be so controlled as to lead to the larger consumption of a pure and better product. It would be a bold and excellent thing if some city or town would purchase and run its own herd of cows with the object of supplying its citizens with good, clean milk. Any small financial loss would be amply repaid by the improved health and increased feeling of security of the community.

Whereas the economic side of food supplies must obviously always be one of vast importance, the question of personal profit plays far too great a part in feeding arrangements. This is beginning to be recognized by the setting up of the Food Council to investigate the relation of cost of food to wholesaler and retail profits. As time goes on the importance of the question of pure food and food marketing will be more and more recognized, and State schemes for meeting the situation will undoubtedly be developed. It is neither desirable that any particular food should be reduced in or eliminated from the diet under the influence of private individuals and companies, nor that it should be foisted on to the public by other individuals for similar reasons. Both of these actions are possible. An example of the first of these is seen in the gradual reduction of an excellent food in the dietary of this country in the case of fish, apparently as the result of methods of sale employed by fish retailers. An example of the second type can be seen in the tremendous consumption of pig products and veal in Germany, as the result of the discovery by a strong agrarian movement that the production of these foods is a sounder economic proposition than the production of beef and mutton. If big dietetic changes are desirable they should be controlled by the State, each case on its own merits, after the best advice has been taken from both a nutritional and a financial standpoint.

#### Cooling Facilities

This part of the problem involves a discussion as to whether it is desirable for the State (a) to play a greater part in the teaching of cookery and (b) to provide means of cooking food for public consumption. I imagine that greater facilities for the teaching of cookery will be pro-

vided by local authorities as the demand for such by the public increases. Better education and greater realization of the importance of proper feeding will no doubt hasten this demand.

The second point—namely, the provision of means of cooking food by the State—seems to me of greater interest. It would certainly be a method by which many individuals would obtain not only better cooked food, but also one by which they would have the chance of getting a greater variety of more wholesome food. The modern practice of consuming great quantities of preserved foods, the large trade carried on by cookshops in poorer areas, the increasing opportunities afforded for the purchase of expensive cooked foods, seem to indicate the desirability of the setting up of public and official organizations where people can obtain food altered, prepared for consumption, either at home or on the premises where cooked. Experience of this type of organization was obtained during the war, and no doubt others will be in a better position for expressing an opinion as to the desirability or not of the State taking up this matter.

#### Summary

1 Increased interest of the State in nutritional matters is very desirable, and would lead to untold benefit to the community even if only the knowledge of dietetics already established were utilized.

2 The mechanism for State research on nutrition is already well established in the Medical Research Council, the Empire Marketing Board, and the Board of Agriculture, but greater activity and closer co-ordination of the investigators is necessary.

3 The present interest and powers of the Ministry of Health should be greatly extended, and the first step in this direction ought to be the setting up of a Board of Nutrition consisting largely of people actively engaged in nutritional research with knowledge and experience of the scientific feeding of human beings and animals.

4 The Ministry of Health, acting on the advice of its Board of Nutrition, should (a) control the feeding of Poor Law institutions, prisons, welfare centres, and other organizations where public money is spent, (b) issue dietetic instructions to the public, and, where necessary, give the evidence upon which these instructions are based, (c) consider the advisability of controlling food supplies, and especially of increasing the availability of the "protective" foods to the public.

#### Discussion

Dr. EUSTACE HILL (C.M.O., Durham) agreed that careful attention to diet as a result of a sane and helpful effort on the part of central and local governing bodies would lead to an improvement in the general health equal to that which had followed the attention paid to general hygiene. He quoted a remark of Professor McCullum at Baltimore, to the effect that the chief factor in human deterioration in recent times was the unwise choice of food. He cordially supported the recommendation to set up a Board of Nutrition to advise the Government. He did not, however, think that the issue of official statements to the press would be the most effective method of instructing the average parent. There would have to be more personal and intimate touch with the individual. There was an undoubted need for increasing the supply and cheapening the distribution of important foodstuffs, especially fish and vegetables. At present terrible waste occurred owing to the inordinate profits of middlemen and the preference of retailers for large profits on a small turnover to small profits on a large turnover. The development of allotments and the practical instruction of allotment holders would bring about a valuable improvement in the supply of vegetable foods. He also agreed that the making of a profit out of milk contaminated with tubercle is a disgrace to the community, since such milk is not only the cause of very many deaths but also a source of pain and misery that could not be compensated by the amount of pain and misery that could not be compensated. He was convinced of the need for additional cooking facilities in industrial districts—a need that is intensified by the excess of fried fish shops in such localities.

Dr J P KINLOCH (MOH, Aberdeen) took the point of view of the health visitor, with especial reference to the instruction of parents and cooking facilities. A fundamental duty of the health visitor was the prevention of the incomplete conclusions of research workers, not infrequently recorded in the public press being adopted by the housewives of the country, to the great prejudice of the population generally, and the infant population in particular. This point was illustrated by the article made recently on the oatmeal diet, which Dr Kinloch remarked, when balanced with vegetables and milk, ensured normal growth without rickets. An important duty of the State, as represented by the local authority was to convey through health visitors reliable information to housewives concerning the nature of the food that should be purchased and the manner in which the food should be prepared; they had also to teach mothers what was an adequate diet for a child and for an adult. There had been a large increase in milk consumption in the United States during the last two years due to the efforts of health and education authorities. It seemed essential for the health of the community that information should be given especially to mothers, on the kind of food required to maintain health especially in cases of infants and children on ways of keeping food to prevent contamination on varieties of cooking, and on the method of serving and its psychological effect on appetite and digestion. Girls should be taught the elementary principles of dietetics as part of the school curriculum.

Dr CERAUD LEIGHTON (Scottish Board of Health) insisted that the production and distribution of food was a business and the extent to which there should be interference with private enterprise was always difficult to define. The State should to some extent regulate (1) the raw material whether animal or vegetable, from which food was derived, (2) the surroundings in which they were grown, (3) the handling of the materials by people who used hygienic processes, and (4) their distribution to consumers in a clean and sanitary way. The State had already done much on these lines in connexion with the protection of the milk supply, the limitation of preservatives in food, and the Meat Regulations. Dr Leighton believed that there had been more progress in the improvement of the milk supply during the last five years than there had been in the previous fifty, and he was optimistic about the future. The regulations controlling preservatives in food had already caused a great improvement in many foodstuffs, and the inspection of meat was now better than it had ever been. All these were examples of State interference which had been more than justified.

Sir FREDERICK NEWMAN (Ministry of Health) briefly described the action which the State already took in regard to the problems of nutrition. He agreed that nutrition lay at the foundation of the national health. There was abundant evidence that the nutrition of the people was improving; in fact, there was probably no greater recent social advance in any other sphere. He illustrated the activities of the State by five examples: (1) recent legislation for the safeguarding of food supplies, (2) the existence of a special food department at the Ministry of Health, (3) the co-ordination now existing between different central and local authorities, (4) the work of the Medical Research Council and other departments, and (5) the educational work in hygiene which was aided by the State. Much depended on the medical practitioner, who had the best opportunity of teaching the people to rely less on bottles of medicine and more upon suitable nutrition.

Dr A S M MACGREGOR (MOH, Glasgow) said it was difficult to extract from the conflicting views of the experts on nutrition any clearly ascertained facts for presentation to the public as to what constituted a well balanced diet. There were still differences of opinion for instance as to the best method of feeding young children, and he found it hard to believe that Professor Mellanby could be serious in his attack on oatmeal. It must however, be agreed that great improvements in the food of the people had followed recent legislation. The reduction in the incidence

of abdominal and glandular tuberculosis in Glasgow was probably associated with the increasing freedom of the milk supply from tubercle bacilli.

Professor MELLANBY, in reply, said that his views were based on facts definitely ascertained by experiment. If people opposed to such facts their own predictions or preconceived opinions founded only on casual observation, he could not be much impressed. If anyone would demonstrate by a different or better series of experiments that his conclusions were false, he would be prepared to reconsider the whole of his previous work.

## Memoranda: MEDICAL, SURGICAL, OBSTETRICAL

### A COLOUR TEST FOR RADIO SENSITIVE SUBSTANCES

I THINK that a short preliminary note on a new colour test for irradiated ergosterol and certain other radio-sensitive substances may be useful to other workers in this field.

A small quantity of crystalline ergosterol is rubbed with a heated glass rod on a previously warmed microscopic slide, on which a thin, translucent, and adherent band of the rubbed crystals is thus formed. Half the slide is then exposed to the rays from a mercury vapour lamp (Hanovia) for half an hour at 12 inches, the other half of the film being protected from the rays. The whole film is then covered with starch solution which has been boiled in water to which about 5 per cent of potassium iodide has been added. The boiled starch and potassium iodide solution is then applied hot to the film. After a short incubation period, varying from ten minutes to three-quarters of an hour depending on the amount of irradiated sterol present and the concentration of the potassium iodide in the starch solution, the film of ergosterol on the irradiated half of the slide assumes a rich pink colour in consequence of the dissociation of the potassium iodide and the fixation and retention of the iodine as a starch iodide on the irradiated sterol smear. If the film so treated is then irrigated with distilled water the pinkish brown colour will change into the characteristic blue colour of iodized starch.

The test is a delicate one and may be used to reveal the presence of very small amounts of irradiated ergosterol; thus it shows the different intensity of radiation in ergosterol radiated through water and in the air. Some samples of cholesterol fail to give the test.

A considerable number of films of different sterols and other fatty substances have so far been tested with this iodine-starch test. Among these the pink colour changing to blue on irrigation with water has been obtained in definite amounts on the irradiated half of the film in samples of egg yolk, coco-nut stearin cream and certain other fatty substances.

In an address "On the effect of certain irradiated sterols on the cellular constituents of the blood" to the Physiological Section at the Leeds meeting of the British Association, I described an *in vitro* physiological test which depended on the haemolytic effect produced on a suspension in normal saline solution of washed red cells by contact with irradiated but not with non irradiated ergosterol. The starch iodine colour test is a further development of this investigation and will, I hope prove useful in demonstrating the presence of certain irradiated fatty substances without the necessity for resort in all cases to lengthy feeding experiments. The two tests afford mutual confirmation from different points of view.

### FOREIGN BODY REMOVED FROM EAR AFTER THIRTY THREE YEARS

THE following record may be of some passing interest. A woman aged 45, complained of deafness. On examination she was found to have wax in both ears. From one ear, as well as wax, a rounded hard black body was recovered, which had the appearance of a pea. She stated

arthrodesis of the hip was a recent innovation. The procedure which most appealed to him was that devised and practised by Hibbs of New York. Hibbs transplanted the anterior two-thirds of the trochanter, together with about two inches of the cortical bone of the femoral shaft. This bone graft was pedunculated and left with the upper part of the trochanter attached by periosteum and the free end—that taken from the femoral shaft—was laid along the superior surface of the neck of the femur bared for its reception and firmly wedged into a groove cut in the ilium above the acetabular rim. Slight abduction jammed the bone graft firmly into position. Hibbs laid great stress on the careful saving of the periosteum and relied on this structure to form new bone. He peeled it off with care, taking perhaps the outer layer of compact bone with it if it did not strip easily. The arthrodesis or fusion of the spine which Hibbs practised left, when the dissection was complete, a series of spinous processes and laminae cleared of periosteum, which periosteum formed a practically unbroken sheet lining the muscles and soft parts which had been retracted. Bone fusion was proved by clinical examination and skiagram.

The president went on to emphasize the value of arthrodesis in the treatment of painful joints following fracture or other trauma. He believed arthrodesis of the ankle the best procedure to adopt in any old malunited ankle-joint fracture when there was evidence of traumatic or mechanical arthritis. He also followed Wilson of Boston in advocating immediate arthrodesis of the subastragalo-joint for fracture of the os calcis. Arthrodesis of the spine—spinal fusion—was practised in America as the treatment for crush fractures of the vertebrae. The operation devised by Hibbs was the operation of choice, and anyone who had watched Hibbs arthrodesis a spine must feel that the operation was bound to result in solid bony ankylosis. As to the part which arthrodesis could play in the treatment of chronic painful arthritis of the hip, after an experience of arthrodesis of the hip-joints in about thirty patients he could affirm that pain was relieved, although the hip did not always arthrodesis, for the operation might, and frequently did, result in a short fibrous ankylosis. Certain considerations, however, had led him to try out the operation of reconstruction leaving a movable joint. Although reconstruction of the hip was perhaps still in the experimental stage it was well worth a trial. The after-treatment consisted in moderate fixation for a month and then the patient was allowed up. The modern operation of mid-tarsal subastragalo-joint arthrodesis was due to Dunn in this country, and Dunn's method of stabilization of the foot had stood the test of time and gave good function. The speaker's general conclusion was that, while the uses of arthrodesis in the treatment of surgical tuberculosis during the active stage had to be carefully weighed and considered, he felt that in certain directions, notably in the treatment of mechanical arthritis, it could with advantage be practised more often.

Mr R. C. ELKINS said that some seventeen years ago he collected a large number of cases of old excision of the knee, as it was then called, for tuberculosis. In those cases ankylosis had in almost all been attained but the proportion with had deformity was very high. This was due to two factors: interference with growth, and the bending of the bone at the point of fusion. He believed that damage might be caused not only by actually interfering with the growing disc, but merely by going anywhere close to it. In advocating fusion for tuberculo there was some risk of making it a routine operation, to be carried out as a matter of course, and often without care for preliminary and after treatment. Arthrodesis should be regarded as a method of internal fixation, but not as a method of curing disease.

Dr CORPOUS PUGH said that he knew no more difficult disease to control than tuberculosis of the knee which had gone beyond the erosive stage, but cases admitted early, before the disease had progressed so far as a rule gave rise to no trouble. He favoured the method of traction by suspension (described in his presidential address to the Section last year) for securing free movement of the hip-joint, the results had been most remarkable and in no case had the acetabulum wandered. With modern

administrative methods whereby cases were brought into hospital earlier, he believed that arthrodesing operations would be less called for.

Mr GIPPLESTONE held that there was no short cut of any sort to the treatment of surgical tuberculosis. An operation for fusion of a tuberculous joint should be considered only as part of the conservative treatment. He would put the fusion operation at the end of treatment, and perform it only when the joint was limited in movement or destroyed as a functioning joint and when the radiograms showed a considerable degree of diseased bone.

Mr TRETHOWAN expressed some disappointment with the results of reconstruction, on which no one had been keener than himself, and he thought it rather a melancholy confession if arthrodesis had to be acknowledged as the only mainstay in orthopaedic surgery. Mr NARRACON DENN said that arthrodesis had proved valuable in Charcot's disease. Mr ALAN H. JONES mentioned that men in the Air Force who had sustained crush fractures of the vertebrae were still apt to complain of aching even after prolonged rest upon the back followed by the provision of the most approved form of spinal support. Mr H. A. T. FARMING also spoke of the advantage of "arthrodesing" a Charcot joint case, which he had found to be an excellent procedure.

Mr ROWLEY BARTON, in reply, said that he was far from advocating wholesale operating on tuberculous joints in children, but he did not think that the best was being done for the patient if he was kept in a tuberculous hospital to which no competent operating surgeon was attached. He believed that in many cases arthrodesis was really the best treatment.

## Reviews.

### OPERATIVE SURGERY

*The Operations of Surgery*,<sup>1</sup> edited by ROWLAND and TURNER, is now in its fifth edition. The book was originally written by Mr W. H. A. Jacobson and immediately established its position as a favourite—a position which, during twenty years of unremitting revision by Jacobson himself, was steadily maintained. It is too well known to need any description of its general features, but its value is enhanced by certain special features which are scarcely indicated by the title. The operations are described in a manner such as would be expected from so gifted a teacher as Jacobson, but the book contains much more than operative technique: it is recognized that operations often appear from reading and watching to be easier than they really are, thus leading the novices to attempt more than they can manage. Stress is therefore laid upon indications for and against operations and special attention is called to the possible pitfalls and errors, difficulties and anxieties that may beset the path of the beginner. For example, under the heading of acute intestinal obstruction we read that "the grave urgency of this condition is not yet sufficiently recognized" and accordingly with a view to ensuring earlier diagnoses the signs and symptoms and the differential diagnosis of the condition are discussed in detail in addition to the technique of the operations for its relief.

A feature of the book is the evident care that has been taken to make the illustrations worthy of the text in addition to the insertion of many new figures; the previous illustrations have in many instances been redrawn, where it was deemed that improvement could be effected. Many changes have taken place in the twelve years that have elapsed since the issue of the last edition necessitating numerous alterations and additions in many parts of the work, some of which may be alluded to. In Volume I the section on transfusion has been enlarged and brought up to date, an account of wound of arteries by modern bullets has been added, the methods of bone grafting have been

<sup>1</sup>*The Operations of Surgery*. By R. P. ROWLAND and R. E. TURNER. London: F. & S. L. and Philip Hart, B.Sc. 1927. F.P.C.S. Series. Seventh edition. London: J. and A. Churchill, 1927. (Part 8 of Vol. I, pp. ix + 160, 456 figures. Vol. II pp. vi + 66, 373 figures. £3 10s. the two volumes.)

redescribed, the account of bullet wounds of the skull and brain rewritten, and a section added on the treatment of trigeminal neuralgia by injection of alcohol. Considerable additional detail has been given on the subject of plastic operation on the face, a branch of surgery which was revolutionized during the war, the section on the operative treatment of injuries of the chest has been rewritten, and recent methods in the surgical treatment of tubercle of the lung and bronchiectasis have been inserted. A section on periaortic sympathectomy for threatened gangrene of the extremities has been added, and those on operations on the semilunar cartilages and on the technique of bone-grafting have been rewritten.

The alterations and additions in Volume II include Mr. Philip Turner's description of the operation of simple removal of the sac in inguinal hernia, additional details regarding the pathology and treatment of subphrenic abscess, the cautery treatment of gastric ulcers, introduced by D. C. Balfour, and a greatly extended account of the radical operation for jejunal and gastro-jejunal ulcer. The following brief summary of the author's personal experience in the treatment of gastric and duodenal ulcers is of interest: with gastro-jejunojejunostomy for duodenal ulcer there were 85 per cent of cures (mortality 1 per cent), with gastro-jejunojejunostomy and cautery excision for gastric ulcer, 75 per cent of cures (mortality 2.5 per cent), with partial gastrectomy for gastric ulcer, 90 per cent of cures (mortality 7 per cent). In discussing the subject of peptic ulcers, the authors observe that the term "perforation" should be reserved for those cases in which there has been a local or general extravasation of the contents of the perforated organ into the peritoneal cavity, and should not be applied to adherent ulcers penetrating the adherent walls without extravasation. Statistics, especially in America, are vitiated by the loose use of this term. The Polya-Balfour method of partial gastrectomy, as modified by Moynihan, has been added to the volume, and a section on simple tumours of the stomach introduced. Experiences during the war have rendered a revisiting of the subject of gunshot wounds of the abdomen necessary, a section has been added on wounds of the diaphragm, and the account of diverticulitis of the colon is practically new.

The numerous changes and additions that have been made in the two volumes show that much care has been bestowed on the revision in order to bring it up to date. One of the main objects of the work, as stated by the authors, has been to give credit and fair criticism to any new operation that seems worthy of consideration and trial, some of the methods suggested will survive, others will be rejected after a cautious trial.

#### TUBERCULOSIS IN CHILDREN

To a "library of tuberculosis," edited by Professors Chantemesse, Poncet, and Collet, Drs. Pehu and Dufourt have added a very complete treatise entitled *La Tuberculose médicale de l'Enfance*. They furnish a synopsis of current pathological and clinical views on tuberculosis in children, with special reference to pulmonary and generalized forms of the disease. After a historical introduction, and a chapter on the frequency of infantile tuberculosis, they discuss the vexed question of heredity under the headings "Heredity of the seed" and "Heredity of the soil." Of the former kind they consider that the only mode of inheritance of any importance, though even this mode is rare, is contagion through the placenta. They describe the researches of Calmette and others on the passage through the placenta of a filterable virus of tuberculosis. With regard to the heredity of soil, the authors consider that inherited predisposition to tubercle is far from being proved, but they think that tuberculosis in progenitors is a cause of dystrophic lesions in descendants, though less frequently than has been asserted.

It appears that infection through cow's milk is extremely rare in France, but Drs. Pehu and Dufourt are not prepared to deny its occurrence, though deprecating exaggeration of the danger. They have come to the conclusion

that pulmonary tuberculosis is almost always of human respiratory origin, though sometimes arising from infection into the intestine of human or bovine tubercle. Abdominal tuberculosis, on the other hand, they find to be predominantly of digestive origin.

A large section of the book is devoted to the pathological anatomy of the disease, and this is followed by a description of the clinical features. Here a division is made into the tuberculosis of nurslings and the tuberculosis of what is called in France "second childhood," the distinction between the two groups being the far greater resistance offered to the infection by older children. In this connexion the authors assert that if it is considered necessary to retain the word "pretuberculous" it must be understood that in the majority of cases the pretuberculous person is already tuberculous in the bacteriological sense of the word and under the influence of bacillary poisons.

As the use of the word "scrofula" has been almost given up in this country, the chapter on the condition so described by foreign observers should be interesting to the Englishman. The authors are convinced that scrofula is a special affection arising from an exudative lymphatic diathesis. The cuti-reaction to tuberculin of sufferers from scrofula takes a special form, being always positive, though intense, and even violent.

Under the head of treatment the various measures commonly used are discussed. Drs. Pehu and Dufourt are strongly opposed to seaside climates for nurslings with clinical or radiological signs at the apex of the lung or in the mediastinum. Heliotherapy is not for indiscriminate use, it may be dangerous. Tuberculin as a therapeutic agent is discussed, but the authors reserve judgement since, notwithstanding optimistic conclusions reached by some who have employed the remedy, there are many detractors, though it is suggested it is possible that the opinion of those who distrust tuberculin is due to excess of prudence in its use.

The book is a useful compendium of research and knowledge of tuberculosis in children. An extensive bibliography is appended to the volume, together with a number of reproductions of many photographs of chests.

#### LECTURES TO GENERAL PRACTITIONERS

The Medical Society of the County of Kings represents organized medicine in the borough of Brooklyn of the Greater City of New York and now, after a continuous existence of 105 years, has a membership of 1,700. Among its varied activities is an annual course of lectures of practical value to general practitioners by men of recognized ability and teaching experience. The second series of these *Practical Lectures on the Specialties of Medicine and Surgery* contains contributions from thirty-seven authorities on most diverse subjects. Professor G. W. Cline gives his experience of 13,988 operations on the thyroid gland, 95 per cent being thyroidectomies for hyperthyroidism, for this condition, which is not primarily of the thyroid, and may be induced in adults with adenomatous goitres by continued iodine medication, the only satisfactory treatment is, he says, operation. Dr. M. A. Rabinowitz, in a lecture on hyperthyroidism, insists that iodine should be given only as a prophylactic and curative agent in the diffuse colloid goitre of puberty and never in localized adenomas, but he differs from Cline, who has no good word for any treatment, in recommending irradiation therapy. That surgery is the best treatment for hyperthyroidism is also the opinion of Dr. F. H. Lattes, who discusses on the varieties and treatment of goitres.

Dr. Timme, lecturing on endocrinology, discusses the bearings of the status thymico-lymphaticus, which he prefers to call the status hypoplasticus in agreement with its originator of this term, Bartels. The therapeutic value of non-surgical drainage of the biliary tract is set out by Dr. B. B. Vincent Lyon of Philadelphia, who has done much to elaborate this technique, and Dr. H. L. C. who is the author of a book on diathermy, gives a summary of

physiotherapy Dr J Eastman Sheehan's account of the present position of plastic surgery is very generously illustrated by 16 figures, and shows that, though the war gave opportunities for improvement in the technique, there is much need for plastic surgery in civil life, especially for the relief of the after results of burns. The practical aspects of the cancer problem are handled by Dr W S Brambridge, and Dr F Carter Wood describes the uses and limitations of radiation in malignant disease. Other lectures deal with the newer remedies, the colon, the doctor in court, fits, gits, puerperal infection, the toxemias of pregnancy, the cold of children, and periodical health examination. This list does not nearly exhaust the catholic nature of the lectures in this well brought out volume.

### STERILITY IN WOMEN

Dr CATTIER, to whom was awarded a few years ago the Michelin prize on the depopulation problem for an essay entitled 'Des Bebes, s'il vous plait,' has now written a book on female sterility with the subtitle "maternity restored." The very fact that it is written by a medical representative of the group in France that is trying to combat the effects of birth restriction in that country gives the book a character of its own, and it must be regarded as a medical treatise on sterility and as advocating the views of a particular sociological school.

The investigation and treatment of sterility in women is considered fully both from the preventive and curative standpoint, and with the enthusiasm of one who regards his subject as of the utmost importance for the welfare and betterment of the race. Recent methods, such as those of Rubin and his followers for investigating the patency of the Fallopian tubes by insufflation or the injection of opaque solutions, are included, as well as details of treatment by general hygienic measures, organotherapy, massage exercises, hydrotherapy, pessaries, artificial insemination and various surgical procedures. Considerable space is properly devoted to the treatment of local inflammatory conditions of the lower tracts of the genital tract in order to lessen the incidence of the chronic uterine, tubal, and peritoneal conditions that interfere with the reproductive function. There is little critical discussion of the relative value of the various procedures and forms of treatment advocated, and it is not easy to discover how much is to be expected in the way of results or how to make a selection from among so many. There is a concluding chapter on the amelioration of the race, the modern marriage, eugenic selection and prenuptial examination, for the last of which the author shows no enthusiasm.

The book is typically French in style, with many curious asides and digressions that lighten and enliven what would otherwise be heavy medical reading. It will have a particular interest for those who wish to study the question of depopulation, or to learn the views of a medical practitioner who is among those who have seen reason to take alarm at the effect of the restriction of families in a country that has practised it widely and for long.

### FACT AND FANCY

THERE are some who deny that the world is round and some who still believe in the mystery of Joanna Southcott's boxes so that it is not altogether a matter of surprise that there are others who deny the facts of physiology and of experience. There is a book before us written by one W H BATES, M.D., which for boldness of denial and strangeness of assertion rivals the others. The title of the book is *The Cure of Imperfect Sight by Treatment without Glasses*, but that on the cover is 'Perfect sight without glasses.' The author would have us throw away our useful glasses, and beguile ourselves into the belief that we see better without them. Trial shows that we do not and that his alleged treatment is no more than a beguilement of the

does not stand the test of experience. To practise judgement of what is seen is one thing to see that same thing better is another, to 'palm' the eyes—otherwise make use of familiar and refreshing magic—is one thing to alter an anatomical defect another. But then this author denies anatomical facts, and alleges that all errors of refraction are merely functional. Strangely enough, he admits the use of glasses for patients who have no lenses as the result of extrinsic operation, but denies the use of the lens in accommodation, despite the evidence of Purkinje's figures, which he has heard of, for he reproduces the classical picture in his pages. His only extension to the assertion of the value of small print, even that which is so small that it cannot be read, "those who cannot read such type may be benefited simply by looking at it." Excessive light, he alleges, is not injurious, but actually beneficial, therefore look open-eyed at the sun. Reading in bed is "beneficial rather than injurious," perhaps when the print is not seen! But, strangely, black has its virtues. It is possible to perform surgical operation without anaesthetics when the patient is able to remember black perfectly. Perhaps the author got somewhere near a truth in a sentence in the last paragraph of this book. "The fact is that, except in rare cases, man is not a reasoning being."

We met one of this cult recently a parent had been summoned to attend a certain place owing to his persistent refusal to provide his child with glasses for school use. The child had myopia of 3 D, without glasses vision was 1/60, with glasses 5/6. The child appreciated the value of the glasses but the father would not allow them to be worn, alleging other treatment. But the recalcitrant parent wore glasses himself for an equal degree of myopia. It seems a pity good paper should be wasted on such a book, or that our columns should give space to its notice. But there have been inquiries, and so this review.

### NOTES ON BOOKS

THIS is the season of mellow fruitfulness in the publishing world, when new books and new editions fall thick and fast upon us. Among the imported fruits of learning and industry we welcome a further edition the fourteenth of the *American Illustrated Medical Dictionary*. Known to many in this country as the Big Dorland to distinguish it from its diminutive elder brother the Little or Pocket Dorland. The present issue has been thoroughly revised by Dr NEWMAN DORLAND in collaboration with Dr E C L MILLER, professor of bacteriology and biochemistry in the Medical College of Virginia. It is stated in the preface that there are over 2,000 new terms in this edition and many definitions have been rewritten to bring the terminology in accord with the latest accepted ideas. The spelling of course follows American usage. Many new line blocks have been added in order to elucidate definitions and emphasize points that can be well born in this way. Since it first appeared twenty-seven years ago the work has grown continuously. The fourteenth edition contains nearly twice as many pages as the first but owing to the use of thin but opaque paper the thickness of the volume has not increased in proportion. The English speaking medical profession owes a large debt to Dr Dorland for the high standard of care and accuracy maintained through successive revisions.

The second edition of Dr ALEXANDER's textbook on diseases of the ear in childhood is really a complete work on otology with special reference to the anatomical and pathological peculiarities presented in the young. The first edition appeared some fifteen years ago. The frequency with which the ear is attacked by disease in childhood may be the justification for this rather official restriction. But as we have indicated the book is far more comprehensive than its title the only important omission to be discovered being the absence of any reference to tumours and other diseases of the eighth nerve. There is no call for criticism for the work which is dedicated to the memory of Adam Politzer is written by one of the great masters of otology is of a reasonable size and is adorned with many fine illustrations.

## PREPARATIONS AND APPLIANCES

*"The Wedgeway"*

MR. A. LOWNDES YATES, F.R.C.S. (Birmingham), has designed an instrument to replace the wedge which it is customary to employ whenever the teeth of an unconscious patient are tightly clenched and respiration is obstructed. It consists of a tongue depressor having a double duck. The thin end is passed between the teeth and, when pushed further, opens the mouth, at the same time affording an airway. If the tongue is the cause of the obstruction it can be depressed, provided that the "wedgeway" is introduced behind it. The instrument (Mr. Lowndes Yates writes) thus affords a ready means of dealing with almost every emergency which may arise from respiratory obstruction in unconscious persons. It is anticipated that it will prove specially useful to nurses who have charge of patients during recovery from anaesthesia, it has the further advantage that it is inexpensive and cannot get out of order. The wedgeway is obtainable from Messrs. Allen and Hanbury, Limited, 48, Wigmore Street, W.1

## THE LONDON MOTOR SHOW.

## SOME POINTS FOR MEDICAL MEN

By H. MASSAC BUIST

THE twenty-first international motor car show opens at Olympia, Kensington, under the patronage of the King, on Thursday next, October 13th, and will remain open, the Sunday excepted, until 10 p.m. on Saturday, October 22nd. Various changes have been made in the organization, all of which are to the good. Thus in former years the public have not been admitted to the exhibition until the Friday, the Thursday being called a trade and press view day. But what was intended to be purely a business facility was so much abused that the situation became unmanageable. Many thousands of persons concerned neither with writing about the exhibition nor with motor trading sought and secured admission. The Society of Motor Manufacturers and Traders has arrived at a happy solution of the problem. It will make no change in the charge for admission on the days which have hitherto been available to the public and will again be available, but on Thursday next the exhibition will also be open to the public, instead of closed as hitherto, and it will be possible for anybody to enter the building by paying ten shillings at the turnstiles. Thus the congestion problem will be solved, and through the added revenue still further advancement of automobilism will be possible for the only body which has the opportunity to do this, by such means as subsidizing institutions that cannot afford to pay for the investigations they were established to carry out, encouraging certain classes of competitions for the evolution of the machine, and holding exhibitions concerned with branches of automobile enterprise which do not draw large numbers of the public and on which there is therefore a loss.

## IMPROVED STAND SCHEME

Another improvement of note may be observed by anybody on entering the building. It concerns the lay-out of the stands in the car section. As far as possible island stands are being provided along a continuous central gangway from the new entrance off the main road to the central gangway in the main hall. Another set of regulations is designed to remedy the second of what I would call market-believe British motor cars. Not until this year has there been anything approximating to a satisfactory definition of what constitutes a British-built vehicle. In that connexion the society sent to America a delegation which has done very satisfactory work in clearing up some parts of the problem. Next week in respect of every motor car shown at Olympia there will be stated on every show card, price card, or other form of notice submitted the following particulars: "Chassis made in —" and/or "carriage work made in —" Where the exhibit displayed is wholly the product of one country, one announcement, "Made

in —," may be displayed. In regard to accessories, components, and tyres, similar information will be conveyed (a) by means of a card attached to every item exhibited, (b) on a schedule of all the items exhibited, prominently displayed upon the stand as approved by the exhibition manager, and (c) by one notice "Made in —," where the whole of the exhibits are products of one country. The most difficult point to settle in the past has been: "What constitutes a British-made car for the purposes alike of trading and of exhibition?" Thus some machines which have been only assembled and packed in Canada have actually entered this country as British built. The new rules lay down, however, that the chassis and carriage work of complete cars shall be regarded separately, and that the country of origin shall be that within which the exhibits have been mainly produced, except that claim shall not be made for origin of any country within the British Empire.

## GERMANY'S RE-PATRI

The forthcoming exhibition will be further notable in the history of the motor business in this country because, for the first time since 1913, German chassis and coachwork and other automobile goods are admissible and will be displayed. Thus there will be shown the six-cylinder Mercedes cars of various sizes, including the very high powered supercharged types, and which have perhaps in "academic interest" for medical men, since this year we have in the Le-Francis a British car standardized with a supercharger. Mercedes pioneered this development as far as standardized motor car practice is concerned. I could describe the effect, from the driver's point of view as being that when he has attained a certain speed and thinks he has got the utmost out of the engine, by further depressing the accelerator pedal so as to bring the supercharger into use he suddenly gets the impression that a second engine has been insinuated under the bonnet of the car. Then the need for gear changing is greatly reduced. At present, however, such a well-proved device is available only in these very expensive cars which do not come within the purse-range of the average medical man, and its use sets up a morning noise.

## THE FORD SITUATION

As in former years Ford cars will be conspicuous by their absence, because this firm has never signed the Society of Motor Manufacturers and Traders' bond. But, largely owing to an ingenious publicity campaign, many medical motorists are curious to know about the promised new style Ford car. It has even been hinted that it would be exhibited elsewhere in London concurrently with the Olympia show. This, however, will not be the case. I have stated, as a result of private (as distinct from official) information from America, that the new Ford car is not even in production there, though large numbers of some of the parts have been going through the shops. So far approximately 350 of the new engines and chassis have been built and stored, pending Mr. Ford's final decision. As engine production works in Detroit are in readiness to get going on a proposed schedule of approximately 300 cars a day, which is a very small output for Ford. Much has yet to be done before big production can be attempted. Even in America Ford agents are considering that they will be lucky if they get more than a sample car and a few spare parts during the rest of this year.

Changes are being made, and tests carried out in connexion with pistons and connecting rods. A good deal of experimental work is still going on. Instead of all the pistons, for example, come on the Lynter principle are being considered. Connecting-rod changes are being investigated, chiefly with a view to reducing cost, for it is intended to produce a better product at approximately the same price as that hitherto charged for Ford cars. Mr. Ford is satisfied with the cost price, not that everything has yet been done to effect savings that will enable the car to be marketed at as low a figure as may be possible. A very important point is that, in connexion with his engine, he has developed a new steel treatment, which is intended to produce a metal of great strength and toughness. If this is so it will be a big accomplishment, and will affect the sale of the new car just as the former method of steel

manufacture made possible the model "T." The new treatment of steel, together with the discarding of the use of malleable, in the new car has made possible a rearrangement of important parts of the factory plant, which, it is under-stood will greatly reduce overhead charges and cut down the amount of labour needed. A like procedure is being followed in regard to all details of the works equipment, machine groupings being made to effect saving in operating costs. In fact the fact that certain parts are now being made in three operations which formerly required six.

#### UNBREAKABLE GLASS AND LABORATED DYES

Again the glass plant is being employed on a much reduced scale pending the result of experiments now in progress concerning an unbreakable glass. The company is still awaiting the receipt of a number of important new machines that will play a big part in quantity production schemes. Practically all the through-over plans of production and factory equipment have now been completed. Plant for manufacturing lacquer for body finishes has been installed, and the company is making experiments on a large scale in the use of synthetic dyes from Germany. To lessen high duties on importing these materials the liquids in the dyes are evaporated off before shipment, so that large quantities may be sent across the Atlantic in concentrated form.

Seeing that the new Ford engine designed in America is 1/8 in wider in the cylinder bore measurement, and that the piston travel is half an inch longer, it would appear to be an impracticable type for sale in this country. Although it follows conventional construction and has an L-head, a pump-assisted cooling water circulation with a single piece two-bladed propeller-type fan and oil pump circulation at the base of the crank case. A five-bearing crank shaft of a much heavier type than in the model "T," and counter-balanced by the use of circular crank cheeks joining the crank pins, is another feature. But for new Fords to be built in this country and for the European markets an engine of about £12 taxation rating is in hand. The new type generator to be used on all Fords is equipped with oilers self-lubricating bearings but the old Ford starter will be retained. An improved steel selective type transmission scheme, that practically reproduces the Lincoln scheme on a lesser scale, is a feature which will be a clutch on the Lincoln principle. The front axle will be heavier than in former Ford practice, on account of the provision of front-wheel brakes of the internal expanding type equipped with two-piece steel brake-shoes on each drum and achieving a total braking surface of 144 square inches. Further what Americans call parking brakes and we call hand-controlled brakes are mounted on the two rear wheels. The radiator and hood will be larger than in the model "T" Ford and with round line. The top will be lower hanging the car nearer the ground and the springs will be flatter. The wheel base will be 110 inches, and the hubs will be larger with roller bearings in the wheels. The steering wheel will be of the irreversible type. Perhaps the most important point however is that contrary to the practice hitherto pursued by Ford plans permit of the new type of car being developed and changed in detail in exactly the same way that other motor manufacturers operate. Therefore, Ford cars may be presented in a different form from year to year, according as changes in demand come about.

#### NEW CAR WITH SIX AND EIGHT CYLINDER ENGINES

Olympia will certainly provide greater mechanical novelties than will be found in the new Ford car in spite of the fact that the notable new Durant series of 18-h.p., six-cylinder engined low priced external expanding four wheel braked Pugby cars listed at more £285 to £365 complete, will not be shown, being sixth on the society's rating list of would be exhibitors. Nevertheless, there will be many entirely new vehicles in almost all categories though the majority have six-cylinder engines. But no less a constructor than Wolseley now owned by Mr. W. R. Morris will introduce a 12/32 h.p. 1.5-2 c.m. four-cylinder engined £12 tax four-seater £315 and a four-cylinder car with an overhead valve crank shaft fitted at £235 as a four-seater. Standard will show a four-cylinder 2-h.p. car. Buick will show a four-cylinder car, and Chalmers will intro-

duce a new four-cylinder 9-h.p. car selling at £145 or as a fabric saloon at £160, and also a two-seater 2250 12/35-h.p. model. At the other extreme Daimler brings the V-type six-cylinder double sleeve-valve engined chassis within the purse running cost and coachwork range of a much viler public than the nominal 50-h.p. type. That is now supplemented by a 30-h.p. machine that will be shown at Olympia and an example of which has been ordered by the Queen. It is an admirably flexible and speedy car for the specialist.

Apart from the introduction of some new "straight-eight" American cars—as well as of the Cadillac built V-type La Salle—a notable British supplement to Sunbeam's enterprise in this connexion will be the introduction of an overhead valve eight-cylinder in-line engined nominal 20/60-h.p. Wolseley car. Perhaps I should mention that one of Mr. Morris's lobbies for some years has been the private building at great expense because on an experimental scale of eight-cylinder in-line engined cars he himself being a firm believer in the principle. This eight-cylinder Wolseley is no able for its relatively low cost the bore measurement being 2 9/16 inches and the piston travel 4 inches. The exhibit will show the chassis fitted with a smart covered saloon body of modern type, ample accommodation and luxurious upholstery in the best leather to the high waistline, the upper portion being finished in cloth. The list price is £750 only. The bucket-type front seats are adjustable independently, and the rear seat which accommodates three persons has arm rests on either side. The engine clutch and gearbox are also to be shown as a separate unit. The robust and carefully balanced crank shaft is arranged to run in ten white-metal lined bearings. The high tension ignition has both hand and automatic control, and the patent automatic equalizing carburettor is fitted with an air cleaner. Among new American "straight eights" too, will be found the Marmon and the Auburn, the latter an 8-cylinder car and the German industry contributes a fine example in the three-litre Horch.

#### WHY MORE CYLINDERS?

I indicated in these columns last year that in the near future six-cylinder engines would be in a considerable majority, not as regards chassis models only but also as regards the total number of cars to be built. We have not reached that stage yet because Ford is still rather obsessed with the four-cylinder idea though he is experimenting with six-cylinder engines but that type is being made in greater varieties and also in smaller sizes. Therefore already it is being made available in some cases at unprecedentedly low prices this year—in the new side-valve 1474 c.c.m. Renault Monoxia. Indeed, whether we turn to the American to the Continental, or to the home industries it will be found that most of the entirely new chassis to be shown at Olympia have six-cylinder engines. The reason is that no matter how quickly a four-cylinder engine is made to accelerate still this cannot be done so smoothly nor with such absence of strain to the mechanism as with a six-cylinder machine of equal power because to put the matter non-technically, with a four-cylinder engine the most that can be done is to have the explosion just connecting up whereas those explosions or power pulses, must overlap in a six-cylinder construction. Of course on an eight-cylinder engine, designed and built to possess equal merit, this advantage is still more pronounced. That is why in the luxury car class the eight-cylinder engine is coming rapidly into vogue standing to-day in much the same relation to the six-cylinder type that hitherto the latter has occupied in relation to the four-cylinder engined car.

There is of course no hint at all experimental about the six-cylinder engine. Indeed one might say that in face of our aircraft engine experience, there would be nothing experimental about making an eighteen-cylinder engined car not that such a prime mover is likely to be required for car service though the Daimler double six is not a practical expression of it. Its flexibility and therefore of more top gear drive than is possible with an eight-cylinder engine of equal capacity. The element of doubt about any new six-cylinder engined

chassis must consist entirely in this, that either the designer or the builder, or both, may lack previous experience of standardizing six-cylinder power units. This you has not been without costly illustrations of the fact that one may even have made successfully a six-cylinder engined chassis in the pre-war period, but that that experience will not necessarily suffice when deciding to return to that sort of enterprise after an interval of two or more years.

#### SOME TYPICAL NOVELTIES

By way of illustrating the quite new six-cylinder engined types that will be introduced to the public next week, I may mention the enterprise of the Peerless Motor Car Corporation of Cleveland, Ohio, one of the three foremost high-grade car builders in the United States since pioneer days, in introducing a £435 six-cylinder engined car. Auburn will also show a vehicle with a six-cylinder engine, and Dodge Brothers of Detroit and Toronto will show a new six-cylinder engined range of 224 cubic inches cylinder capacity, having a sturdily built crank shaft, the scheme being standardized with all-steel bodies by the pioneers of that system of construction now taken up by Citroën and by Morris for certain types. This is the first six-cylinder car built by an organization which has produced and sold over two million four-cylinder engined Dodge cars in thirteen years. Among other types, France sends a new 16 h.p. Darracq, and Fiat introduces an £18 tax side-valve six-cylinder engined chassis, which will be shown both in that form and as an interior driven saloon. All the German Mercedes cars have six-cylinder engines, three types—with two-litre, three-litre, and four-litre engines respectively, the two former with side-by-side valves and the last-named with the overhead form—being non-supercharged, and three overhead valve engined types of 33/140, 33/180, and 33/220-h.p. respectively, with superchargers.

New British six-cylinder engined cars of note will be shown by Alvis (a two-litre), Rover (a two-litre), Armstrong-Siddeley (a two-litre 15-h.p. type), Ariel-Aster (20/60-h.p.), Star (18/50-h.p.), and Vauxhall (£20 tax, 20/60-h.p.). The 16-h.p. Austin, announced a month ago for delivery in March, will not be shown.

#### NEW BIG SCALE BRITISH LARGE CAR PRODUCTION

From the points of view of manufacturing and marketing the most conspicuous six-cylinder engined British novelty of the show will be the new Vauxhall. It is the first-fruit of the purchase, two years ago, of that old-established company, always concerned with building a limited number of very high grade cars at Luton where the works have been enlarged to facilitate the production of this new style machine of quality at the rate of 200 cars a week, or 10,000 vehicles a year at a chassis price of £375, or as a Princeton five-passenger touring car, complete with all-welded and other equipment, for £475, as a two-seater for £485, as a coupe for £670, as an enclosed limousine for £520, and as a five-passenger Bedford saloon for £495. From the point of view of the evolution of the motor vehicle this is extremely interesting, because it might be called a Vauxhall car of Vauxhall quality, but of redistributed values. Thus in the past great expense has been incurred to achieve certain qualities required by a very limited section of the motoring public, who are prepared to pay for them and being a price drivers, do not mind changing speed frequently. But in making an appeal to justify such an output as is now embodied on we get a car which, while obviously a Vauxhall nevertheless incorporates certain phases of American practice which have been proved to appeal to the generality of motor users the world over. This is notably so in regard to getting of the back axle and engine speed. The non-technical motorist's ideal is to be able to do what is called "step on the accelerator pedal," whereupon the car should gather speed without misusing the engine. That feature pioneered by the American industry, is to be found in the new Vauxhall car. When, however, we come to such delicate matters as engine balance, engine efficiency for volume and so forth or the four wheel braking scheme or the steering or the freedom from vibration and the manner of the suspension we find American practice far eclipsed and the best European

standards maintained. In other words this is essentially not an American Vauxhall, nor a transatlantic car of any sort, since it is the sort of what American manufacturers can achieve. I consider it a very happy combination of American features that make the widest appeal with European and, especially, British features that are yet unacquainted. Undoubtedly this is a car destined to exercise a very important influence in the full six-cylinder engined car market, for it is preeminently suitable for service overseas as well as in this country. The light steering employs the Miles cam and roller principle. The gearbox gives four speeds forward, though these are controlled centrally in American style. Semi-elliptic springs are used fore and aft.

#### GENERAL DEVELOPMENTS

Incidentally, a study of the products of the American industry reveals a distinct tendency to achieve lower centres of gravity by "double dropping" the frames in the manner exploited in Europe by certain constructors for years past. In regard to covered bodies, the problem of ventilation is receiving much-needed attention in this country. Hitherto one had to get a car specially built if an and light were to be admitted through the roof. Now, however, several constructors will be found offering standardized saloons with non-rattling but movable roof schemes, whereby one can enjoy ventilation and proceed in sunshine without glare, and without draught, because all the windows can be kept closed. Undoubtedly there will be as big a vogue for these bodies as for the fabric type of covered coachwork, which comes into its own this year. We shall see it on cars of all sizes, powers, and costs. Some Americans standardize ventilators at the top of one piece wind screens, which prove admirably effective. Steel building of covered cars also gives some adherents. Liege finish is all but universal for standardized productions, and big advances will be observable—notably on the part of the British industry—in that connexion this year.

Of course, nowadays, nobody should have a car without four wheel brakes. No one system is universal, but a great number of the systems produced by accessory manufacturers, and standardized by the producers of cheap cars, exhibit much-needed improvements in detail. A good deal, however, is still to be learnt about four wheel brakes by at least three car builders out of four. The problems involved are incapable of non-technical explanation, even if a whole article were devoted to them. Suffice it to say that one of the practical features of the low priced four wheel brake equipment this year is that no attempt is made to absorb too much power through those European systems which are not absolutely scientific, and that there is therefore less chance of the driver coming to harm if anything goes wrong. A section of the American industry still continues to employ contracting hand brakes, an obsolete system that has no justification. No motorist should have any car with a contracting collar brake. Instead of checking the wheel, this type either chokes it or lets it run free, sliding being one of the unsatisfactory results.

The advantages of studying overseas conditions in view of the Dominions is revealed in the new series of Hillman cars. These remain four-cylinder engined machines, but they look at least twice as important as before, having larger wheel bases, much better balanced engines, and much better steering. They are now really suitable for service overseas. The wings can be set on without hindering them. Yet this is not an American car, but essentially a British product, as may be judged by the comfort of the seating, for designers can achieve much more accommodation within a body of a given dimension than is the custom in transatlantic practice. Pneumatic cushioning, instead of spring and bar types, gains many adherents for standard practice, and is most advantageous, it is the only type all satisfactory for such hard conditions of use as speed, heavy service. Central chassis lubrication is a notable British adherent in Armstrong Siddeley.

Incidentally, the opening of the Motor Show will coincide with the completion of the building and equipping of factories in this country by three important foreign manufacturers, so that henceforth there should be no monopoly in this industry.

SATURDAY, OCTOBER 8TH, 1927

## THE PATHOLOGY OF THE LIVING

For the subject of his address at the opening of the medical session at King's College London, Sir Berkeley Moynihan chose one rather larger than his title might suggest as will be seen from the full text published in this issue (p. 621) for he discussed not only the training of the surgeon, but also the way in which surgical problems should be considered and he emphasized and elaborated the theme with which he dealt in his Hunterian Oration earlier in the year.<sup>1</sup> He then insisted on the importance of observations made at the time of operation on living human bodies which have enabled surgeons to study what he happily calls the pathology of the living and which as he holds should prove of the first importance in the future advance of our knowledge of anatomy physiology and pathology.

Lord Chancellor Thurlow's rough denial of the right of surgery to be called a science to which Gunning so effectively retorted was not without some justification at that time, and despite the enormous improvement which the nineteenth century witnessed surgeons have perhaps been too ready to accept the position of mere executants and to leave science to the physiologists and pathologists. The growth of knowledge, which had become too much for one mind to grasp in detail and the necessary development of specialism in the ancillary studies encouraged this attitude. Sir Berkeley Moynihan however did not convey the impression that he would have the surgeon able to compete with the bacteriologist and biochemist in their work but that he should recognize and avail himself of the great opportunities of fruitful observation which the practice of surgery affords. It is not too far fetched an inference to conclude as Sir Berkeley Moynihan has done that such a change in the surgeon's outlook is in principle only a return to the methods of Hippocrates and Galen whom he claims as the parents respectively of inductive and deductive reasoning and as indubitable members of our profession. Whether these authors of the theory of the four humours and of all its dependencies will be accepted by philosophers and medical historians as the only begetters of these logical methods may be at least doubtful but we think that the claims of Aristotle who was trained as a physician and was a great comparative anatomist should not be passed over in this connection. Sir Berkeley Moynihan sets a high ideal before his colleagues and students when he claims for surgery the status of a science of exact observation and of inductive reasoning and asserts that it is a method of seeking the cause no less than the remedies of many diseases. Looking at his retirement in this light the surgeon ceases to be the mere handicraftsman and is able to go alone as an explorer and discoverer without diagnostic support from the physician. Experiments upon living animals have been of the first importance and the greatest value in the study of normal tissues and organs and of their reaction to injury or infection and a very large part of the advance of the last hundred years has been

due to them but those who have had to do with diseased organs and tissues have found that there are limits beyond which the analogies of healthy parts will not carry them. Very many of the causes of disease in the human body are of a chronic and often obscure kind and their conditions cannot be reproduced at will in other individuals especially when as usual, those individuals belong to another species. Just as Lister by preventing sepsis made experimentation on living animals—biological research as Sir Berkeley Moynihan calls it—safe and generally painless so also the new weapon of direct research upon man during remedial operations or after grave injuries is forged by him alone. As far as we know Lister never performed an abdominal operation, yet the most obvious triumphs of the method of direct research have been won in the abdomen where duodenal ulcer was practically unknown except as a pathological rarity until surgeons aided by radiologists, revealed the frequency of its occurrence as well as many of the conditions which favour its development or accompany it. Sir Berkeley Moynihan made an emphatic protest against the performance of short-circuiting operations in cases in which no definite lesion has been found to justify them. Such operations at one time had become far too common so much so that a French surgeon has written a book entitled *Gastro-enterotomy a disease*. The result of his study of the pathology of the living has convinced the President of the Royal College of Surgeons of the accuracy of Dr. William Hunter's observations and of the correctness of his inference that much disease in the body is due to far away and in themselves apparently insignificant foci. Yet Hunter has had to fight hard for a quarter of a century and his case should be a warning to us not to reject or neglect new ideas because at first sight they may seem strange.

Sir Berkeley Moynihan had a good deal to say about routine operations and the evils of merely imitative surgery and here we think that his saying is too hard for most of us. No doubt the man who is content merely to imitate the operations of a master and who does not want to improve upon them will not make startling discoveries or do things great in any way but in the dull round the common task a great deal of routine is unavoidable. When Sir Berkeley's colleague at Leeds Mr. A. T. McGill discovered that the enlarged prostate gland could be shelled out of its capsule he made a great and original discovery by which those who followed him have profited but they could not fail to be imitators and they and their like have sensibly diminished the mass of human suffering and lengthened many lives. The same may be said of other operations. Moreover Apollo's bow is not always strong and only the few very elect can always be striving for higher things. Therefore we would enter a plea for the capable but merely imitative surgeon for there are not nearly enough geniuses to go round and perform the batch necessary surgical operations. But as to the insufficiently trained surgeon who is unconscious of his own deficiencies Sir Berkeley Moynihan's denunciation of him and his doings will we do not doubt be generally approved. Though it is not given to all of us to be keen observers able to recognize and pick out from the myriad pebbles on the shore of the sea of knowledge the one scientific gem of purest and rarest wished up by the waves or dredged by another secker from the unathorned depths of the unknown yet all may strive to cultivate their talents so as to acquire the power of grasping truth when it is presented to them.

<sup>1</sup> BRITISH MEDICAL JOURNAL, February 19th 1927.

## FOOD SUPPLY AND THE STATE

THE Section of Preventive Medicine at the Annual Meeting of the British Medical Association at Edinburgh discussed the question "What duties has the State in relation to the nation's food supply?" Professor Edward Mellanby introduced the discussion by a paper which is printed at page 633 of this issue. The paper is so suggestive and provocative on a matter which is becoming almost daily of more and more importance, and is rapidly being recognized as such, that it is almost a duty to direct attention to it. Moreover, it may be of advantage—with a view to some practical outcome—to make certain distinctions, and clear the ground of some possible misunderstandings, if the subject is to be regarded purely as a question of preventive medicine and public health.

As Professor Mellanby points out, "the duty of the State" is an ambiguous phrase, but even if it be taken to mean "what an ideal State should do" in this matter, not everyone will agree that it is desirable for the State to perform all the functions which he would appear to assign to it. An individual's conception of the duty of the State with respect to food supply and cognate questions will necessarily vary with his general political ideas as to the relative position of the State and the individual citizen as regards other matters—as to whether, as is commonly held in this country, the State exists for the sake of the individual, or whether, as is the confessed belief of some foreign Governments, the individual exists for the sake of the State. A perfectly well nourished citizen is no doubt desirable in either case, but it may well be held that something less than perfect health with reasonable liberty of individual action is even better than perfect health secured by the almost complete suppression of individual liberty. Of these questions some are political and others economic, and they must be separated if there is to be a profitable discussion on the practical duties of the State as to matters connected with food supply in such a community as ours. As an example of such confusion of thought we may take a statement which emerged in the course of discussion at Edinburgh, though it was not made in this crude form by Professor Mellanby himself. "Making a profit out of milk contaminated with tuberculosis was a disgrace to the community, since such milk was not only the cause of very many deaths, but of an amount of pain and misery that could not be computed." Surely the deaths and the misery are caused by the tubercle bacilli, and not by the fact that a profit may be made by the sale of milk which happens to contain them, and the sale of such milk might be regarded as a disgrace to the community even if the State or a local authority were selling it at a loss. There is, too, no guarantee that a dairyman or a milk roundsman employed by the State would be any more clean or honest than one employed by a company. The question of the propriety of private trade for profit especially in those things which are necessities of life is a highly controversial political subject which it is desirable to keep quite distinct from the question of what action can be taken by public health authorities—central and local—to see that food supplies are pure. The latter is the public health problem.

Again it is no legitimate criticism of the State, or of a Government department, that it does not make itself responsible for *ex cathedra* statements of what is to be regarded as the final truth concerning dietetics, or on other subjects which are susceptible of scientific investigation and on which there is not a consensus of

scientific opinion, nor that it does not take steps to keep itself officially informed, even in advance of scientific opinion itself. Professor Mellanby seems to claim that it is the duty of the State to do both these things. He suggests the establishment of a new official "Board of Nutrition," "a strong and representative body of nutritional experts," whose duty it would be to present to the Ministry of Health "new knowledge on nutritional matters" and "the best and the latest advice as to the relative importance of new discoveries," even in advance of their publication by laboratory workers, and prior, therefore, to their discussion in scientific circles, and to issue to the public "an official announcement of the facts" and a reasoned statement declaring the relative importance of all the points raised. A strong case can be made against official action of this kind, though there is everything to be said in favour of State help towards research and State encouragement of the spread of knowledge. Such public knowledge can, however, in our view, be better secured by education and discussion than by the promulgation of official dicta, or by the enforcement of stereotyped official dietaries at prison and Poor Law institutions, and in connexion with infant welfare centres.

If these things be admitted, there still remains a vast field in which State action with regard to food supplies is necessary and can be very effective. There is the securing of a sufficient supply of suitable foodstuffs in the event of dearth from war or any other cause, the enforcement of proper conditions of transport, storage, and handling, the prescribing of a pure and adequate content and condition whether chemical, bacteriological, nutritional, or "vitaminous", the supervising of the living sources, whether animal or vegetable, from which essential food supplies are derived, the active helping of research of all kinds, the encouragement of reasonable health propaganda by public or responsible bodies, the enlargement of educational facilities with regard to domestic and personal hygiene and to the art of cookery, both through the elementary and secondary schools and technical classes, and through school nurses and health visitors and the medical profession. All these are strictly matters of preventive medicine and public health, and offer opportunities abundantly enough for action by the State and by those who are either officially or unofficially concerned therewith, irrespective of any particular political or economic faith, and for scientific discussion free from any undue regard for possibly premature pronouncements of what is to be regarded as orthodox.

## SIGHT AND DRIVING

THERE has been some correspondence lately in the Times on the relation of the sight of drivers of motor cars to accidents in driving, and our contemporary, in the course of a short leading article, said "The view is expressed that 'the vast majority of road accidents are due primarily to defective oversight on the part of the pedestrian or the driver.' The evidence on which this conclusion is based is not given, nor any attempt made to distinguish one kind of ocular defect from another in relation to the cause of accidents but even allowing for these omissions, an issue of real importance has been raised." The caution shown in this comment is wise. Certainly sight is a matter of importance in driving, but to assume that because gross defects of sight make driving impossible and dangerous, therefore smaller defects are responsible for accidents to drivers and walkers, is rash unless the defects in vision are clearly defined. The word "sight" is

connotes ability to distinguish objects of a certain size or fineness of detail. Such a connotation is altogether too limited in this regard. Safe progression for driver and walker in ordinary daylight demands that the sight should have a threefold quality: visual acuity, field of vision, and binocular vision. Obviously a driver must have acuity sufficient to see the pedestrian, but a pedestrian and even a chicken, is a relatively large object to the walker; the car is even larger. The visual acuity demanded by such recognitions is low. The field of vision is another matter. The errand boy walking along the street enthralled in a penny dreadful looks not at passers by nor at the kerbstone, yet he neither humps against nor stumbles at the kerb. His peripheral field (where 'acuity' is negligible) gives him a sense of the position of things that means safety. Binocular vision and balance between the eyes is an even finer matter than acuity or field: it gives the sense of size and distance or position the instantaneous and unconscious judgement of the eye is measured by the subtle feel of the non-ocular effects produced by the combined movements of the eyes together with the impressions of visual acuity and of position in fields. That judgement tells us where we are and where others are. It is the sense which leads to skill in many walks of life and in games: it makes the good shot with the gun, the tennis champion, and the safe flying man. It is also the chief physical asset of the good driver. Yet a fourth requisite is a good light sense—that is, ability to see in a poor light. There is as much variability in this as in visual acuity, but unlike the latter there is no correction for defect of light sense, though it may easily be depressed by poor health or indiscretions. It varies also with errors of focus for the use of glasses reduce it especially high concave and convex lenses; so that the correction of an error of focus by glasses which may give standard visual acuity does not always make the wearer of the glasses a safer driver. Such a bare sketch of what 'sight' is gives but a poor view of its complexity. Nor does it touch upon the interrelation of sight and muscular co-ordination—foot, hand and eye of driver and foot and eye of walker. Nor does it so much as hint at the overriding power of nerve control which is suggested in the term 'reaction time'—that power of response which makes two persons who show a general equality in equipment of organs apart in capability. We recall the facts of physiology because unlike these there is some sense of the complexity of 'sight' and its interaction with body movements, no standard or test of sight of genuine value will be arrived at but a test of some part of the whole will be stressed, such as defective visual acuity (so easy to determine) and a situation possibly more dangerous than the present be produced for a certificate of fitness if it is wrong is an added danger. To call upon the Legislature to institute an effective test of sight for drivers on any scientific scale would be asking an impossibility. A minimum test of acuity, of field of balance and of light sense would take a prohibitive time. But even if it could be instituted we do not believe it would materially reduce road accidents, for we cannot agree with the statement that 'the vast majority of road accidents are primarily due to defective eyesight.' Accidents known to be due to bad sight do occur but they are rare. A man steps in front of a moving car and his record shows that he has already been glaucoma; a woman does the same and she is nearly blind with senile cataract. But for the most part persons with such serious defects keep out of harm's way. Many more accidents are due to a visual anaesthesia—seeing we shall see, and shall not perceive, because the mind behind the eye is away far off from the road. Thus visual anaesthesia or wandering attention has caused the death of not a few drivers and walkers and there is no cure for it. All our reactions vary from

time to time, so that a test one day may be valueless on the next. Ill health, unwise indulgence, and fatigue (such as is caused by too long driving) produce wide variations in 'reaction time.' One driver is made jump; so he handles his car injudiciously and it skids; another becomes too slow and he runs into a collision. The driver who has done a long run has a peculiar risk on entering a vast city like London, he may be tired yet keyed up to his touring speed, and a sudden change to slow and intricate traffic is demanded. The readjustment is difficult, and some drivers are wise enough to stop a minute in order to break continuity. It may be asked: If these things be so what is the use of testing the sight of drivers of locomotives, omnibuses and trams or of 'cremen?' Sight tests for engine drivers and seamen are in a different category, these aim at ensuring two necessities for these men—keen sight for minute or distant objects and for colour. Omnibus and tram drivers' sight must be wider especially the former. Certain companies require tests of visual acuity, but in addition the student drivers are under such observation during their training that there is brought into effect a wide range of tests of field, of balance, and of judgement, so that the unwise man is weeded out early. If a test of eye drivers, besides those of public utility carriages is to be instituted it should follow similar lines. It should be a practical test, and it could be so devised as to include a judgement of reasonable acuity, of good field, of balance, and of light sense in many varying circumstances. All these reactions could be ascertained by a practical exercise not merely in a room with test types. Nevertheless, it would only certify fitness or otherwise at the time of the test and it could give no security for future fitness.

#### INDIRECT ACTION OF IRRADIATION ON THE EMBRYO

For several years before his death Dr. T. S. P. Strangeways had been engaged in the study of the action of radiation upon cells growing *in vitro* and the results of the researches were published in his book on *Tissue Culture* and in two communications to the Royal Society in association with F. L. Hopwood and H. E. H. Oakley. These researches had reference to the direct action of the rays but lately he turned his attention to their indirect action—that is to say that if any which results from the physiological disturbance of the whole organism. In this research he worked in connexion with Miss Honor Fell, Ph.D., and a joint paper has recently appeared in the *Proceedings of the Royal Society* (B vol. 102, 1927), in which the existence of an indirect action is clearly established. The experiments consisted in irradiating foetal eggs which had been incubated for different periods (twenty to twenty-five hours six days, seventeen days) and comparing the histological condition of the embryonic tissues immediately after the irradiation and after incubation had been allowed to proceed for further periods of some minutes, hours or days. In the embryos of twenty to twenty-five hours examined immediately after irradiation the only observable effect was a great reduction in the number of mitotic figures. After twenty-four hours' further incubation after irradiation the tissues had recovered to some extent development had advanced and there was a variable amount of abnormal mitosis but cell degeneration was usually extensive and more prolonged incubation was associated with necrotic and cystic changes. In six-day embryos examined immediately after irradiation mitosis was reduced and broken-down cells were numerous in all the tissues after eighty minutes further incubation mitosis was rare or absent enormous numbers of cells were broken down and the vessels were thrombosed. After twenty-four hours mitosis was absent and the majority of the cells had broken down, causing a partial disintegration of the tissues. The effects were similar, but less

pronounced, in seventeen-day embryos. Destructive changes were more marked in the older embryos, which were more highly organized and in which the circulation was established. On the other hand, it was shown by further experiments that the tissues of six-day embryos, when explanted *in vitro* soon after irradiation, still contained many cells capable of undergoing mitosis and continued growth, and that therefore the cells of a six-day embryo were no more susceptible to the action of x rays than those of an embryo of twenty to twenty-five hours. The exaggerated destructive effects in the case of the six-day embryo appeared to be due to some indirect action, and might not improbably be attributed to the thrombosis. On this hypothesis the destructive changes might be assumed to be caused by the accumulation of toxic products of metabolism or to the absence of the normal gaseous interchange in the tissues. That the former was not the case was proved by explanting normal tissue in an extract of irradiated six-day embryo incubated for twenty-one to twenty-four hours, tissue growth was in no degree hindered under these conditions. On the other hand, the results of experiments in which irradiated embryos were incubated for twenty-four hours while exposed to air (by removing them from the shell) instead of *in ovo*, indicated that the death of the cells was due, in part at least, to an absence of gaseous interchange in the tissues of the irradiated chick when incubated in the shell, the tissues exposed to the air grew readily when explanted *in vitro*. Such inhibition of gaseous exchange *in ovo* would result from the clotting of blood in the vessels shortly after irradiation as above described, although it is unlikely that it is the only destructive effect of radiation, since even in embryos of twenty to twenty-five hours recovery was only temporary.

#### MEDICAL EDUCATION IN THE TRANSVAAL

Dr. Raymond A. Dart, dean of the faculty of medicine in the University of Witwatersrand, Johannesburg, contributed to the *Journal of the Medical Association of South Africa* for July 23rd an interesting account of the development of medical education, including post-graduate teaching, in this part of South Africa. So far back as 1903 the establishment of medical and dental instruction in Johannesburg was projected, and, after some delay, a standing committee for medical education was appointed in the Johannesburg General Hospital in 1914, three years later the School of Mines became the University College, Johannesburg, and the first year of a medical curriculum was inaugurated. A complete dental course was provided in 1925. Meanwhile, regulations for the Diploma in Public Health had been drawn up, and in 1926 post-graduate courses for this diploma were started. Johannesburg offers exceptional facilities for instruction in tropical medicine and hygiene, since it is surrounded by tropical and sub-tropical areas. It is thus the one large centre of European medical training where a wide range of tropical diseases can be studied on the spot where they occur, moreover, it contains a large European population from which post-graduate students can be obtained. Dr. A. J. Oienstem was appointed lecturer in tropical medicine and visiting physician in tropical diseases, and, pending the formation of a tropical disease unit in the general hospital, arrangements have been made for a number of beds to be under his charge. The course of instruction in tropical sanitation and hygiene has been designed by Dr. Charles Porter, one-time medical officer of health for Johannesburg, and the courses in tropical pathology and pathological chemistry are being given by Dr. Sutherland Strachan, Dr. Annie Porter taking charge of the parasitology including protozoology, helminthology, and entomology. The last two teachers belong to the staff of the South African Institute for Medical Research, and are also lecturers in the medical

school. The greater part of the laboratory work of the course is conducted in the Institute buildings with the cordial co-operation of the director, Sir Spencer Innes. Diploma courses in tropical surgery, ophthalmology, dermatology, and pharmacology are being arranged.

#### THE HUMAN LIVER FLUKE

The human liver fluke—*Clonorchis sinensis*—has been known to medicine since 1875, but it is only within comparatively recent years that extensive investigations into the bionomics of this very serious parasite have been undertaken. The most recent and by far the most complete of these is a monograph just published by Drs. Faust and Khaw in Peking.<sup>1</sup> The life-history of this parasite follows the cycle now known to be typical of all flukes—that is to say, it passes an essential asexual part of its life out of the body of the host in a particular species of fresh-water snail. In this particular fluke the myriads of cercariae which escape from the snail either die or become encysted in the flesh or under the scales of some species of fish, and apparently any species of fresh-water fish will suffice as the second intermediate host. On being swallowed by the definitive host the little fluke leaves the cyst, and, crawling up the bile duct, reaches the liver, where it settles down and becomes mature. Like so many of the parasites of man, this species is apparently really a parasite of carnivorous animals, and throughout the Far East dogs and cats are extensively infected. Man is only parasitized in certain limited areas in Japan, Korea, Southern China, and French Indo-China, where he has the habit of eating uncooked fish. Northern and Central China have heavy infections in the intermediate hosts, but there are practically no infections in human beings. Drs. Faust and Khaw are mainly concerned with the infection in China, where the chief endemic centres are Canton, Hong Kong, and other parts of the Kwantung Province. The epidemiological evidence collected by these observers points to the mulberry districts as the important areas of this infection, just as Cort and his colleagues<sup>2</sup> have previously implicated these districts as the centres of hookworm infection in China. The infection is caused by eating uncooked or partly cooked fish, because of taste, or for religious reasons, or to ward off cholera, or even because the cost of fuel to cook the fish is prohibitive. The fish become infected from the snails, which in turn become infected from the mud. In those areas where the human disease is important it is, curiously enough, almost non-existent in animals, and a man must therefore provide his own infection. In India, where animals are heavily infected, fish are also, but they are always thoroughly cooked before consumption. In Southern China, therefore, it is possible to destroy the reservoir hosts in combating the disease, and to concentrate on the human infection. Prophylaxis will develop along several lines—education, sanitation, and specific therapy. Education would consist in teaching the people to cook their fish thoroughly, but as practically all species of fresh-water fish are infected, the eradication of the parasite on these lines would, it is considered, prove very difficult. Nevertheless, cooking would entirely eliminate the disease. An attack on the pre-multiplicative stage in the egg would, it is thought, be more hopeful. Sanitation and disposal of night-soil will prevent the infection of essential intermediate hosts, and Faust and Khaw point out that a considerable amount of human faeces finds its way into the fishponds, and directly or indirectly provides food for the fish. Treatment of this night-soil with 0.6 per cent of ammonium sulphate not only destroys the eggs of the fluke, but actually increases the value of the material as fertilizer. It does not seem to be practicable to attack the

<sup>1</sup> Study on *Clonorchis sinensis* (Cobbold). By F. C. Faust and A. J. Khaw. (Monographic Series No. 8) *British Medical Journal* 1927 i p. 27.

snail intermediary at the present time. No satisfactory drug has yet been found with which to treat the fluke in man, but experiments on animals suggest that gentian violet may provide such a substance. The drug definitely kills the parasite, but before it does so it causes a great rise in egg production. Though the results are promising, it is too early to advocate the use of this drug in human clonorchiasis.

#### ADRENALINE AND VASO-DILATATION

It has long been known that the injection of very small amounts of adrenaline produces vaso-dilatation, particularly in a denervated limb but it was believed until recently that the vaso-dilator effects were secondary to the liberation of histamine somewhere in the body, probably in the lung. Dale and Richards<sup>1</sup> have now shown that the injection of a small amount of adrenaline (0.0004 mg.) into the aorta of an anesthetized cat produces conspicuously larger expansion of a denervated leg than five times the dose of adrenaline injected into the jugular vein. The latent period also is much shorter when the arterial route is employed. These experimental results suggest that the vaso-dilator effects are due to the arrival of the adrenaline itself in the arterial blood of the limb. One argument in favour of the view that the vaso-dilatation is produced by a secondary liberation of histamine in some part of the body has always been the apparent impossibility of demonstrating this effect in a perfused limb. Dale and Richards have now overcome this difficulty, and have shown that when the hind leg of a cat is perfused with fresh, defibrinated cat's blood and the volume of the limb produced by the injection of minute amounts (0.0001 mg. or 0.00005 mg.) of adrenaline into the arterial stream produces definite dilatation followed by constriction. In this case as the circulation of the perfused leg is no longer in connexion with the general circulation there can be no question of the effect being brought about by the liberation of histamine in the lung or in any other organ, and it must be concluded that the vaso-dilatation is due more directly to the presence in the arterial stream of the adrenaline itself.

#### THE BIRTH OF MANKIND

SIR D'ARCY POWER, the surgical leader of those members of our profession who in their leisure hours are peacefully penetrating the realms of bibliography, has now done his colleagues (and particularly those obstetrically minded) good service in publishing, with twelve fine illustrations, the scholarly paper he read to the Bibliographical Society on January 17th, 1927 on "The Birth of Mankind or the Woman's Book". This much sought-after treasure of medical bibliophiles, and the earliest known work in English on midwifery, is a newly translated out of Latin in 1540 by Richard Jones. "A diligent and studious Clarke" from the *De partu hominis* (1532) which in its turn was the translation of *Der Schwangeren frauen und Hebammen* 160 given written in 1513 by Eucharius Rosselin the Stadtarzt or city physician of Worms. It is disappointing that nothing more is known of Richard Jones but there is good reason to believe that his original manuscript of *The Birth of Mankind* is still in existence for it was sold at Sotheby's in 1865, and is probably in a private collection, at any rate, it is not in any of the most likely libraries in this country. Sir D'Arcy Power gives a detailed description of the numerous editions which appeared between 1540 and 1654, and of the last he remarks "The living title-page, which is poorly printed and otherwise quite uninteresting" says "The Fourth edition Corrected and Augmented" It is not the fourth edition, it has not been corrected, and it certainly has not been augmented." The title-page of the first edition—

dedicated to Katherine Howard, who in July of that year (1540) was married to "the most mighty sapient Christian prince Kyngo Henry the VIII"—is extremely interesting on account of its ornaments in four panels, as is shown in one of the seven reproductions of the various title-pages. There is also an interesting account of each of the printers and publishers of *The Birth of Mankind* or *The Woman's Book*, and the reprint closes with a comparison of the ornamental initial letters as a means of distinguishing the various issues. This addendum, which did not appear in *The Library*, must have been a labour, but one of love, and there can be no doubt that this paper, like all Sir D'Arcy Power's writings, proves that the expenditure of much time and trouble on the author's part makes easy and pleasant reading.

#### REGULAR MEDICAL EXAMINATION

A Director of the Family Medical Services, Limited, has taken exception to some comments we made recently (September 24th, p. 560) on an associated scheme entitled the Regular Medical Examination Association. We remarked that there was "some lack of lucidity in the documents issued by those responsible for this undertaking", and we gave as an instance the difficulty we had experienced in finding out whence the new association derived the funds for its subsistence. We now learn that these funds are derived from the fees charged to subscribers for the medical examination, and that it is proposed to pay the doctor who examines the subscriber 6s. out of the 7s. 6d. paid for examination of the first member of the family, and 5s. out of the 6s. for each other member. In the literature submitted to us there was no hint of these deductions from the suggested fees, and in informing the medical profession of the scheme we felt entitled to call attention to this lack of lucidity. We noted also a further point—namely that it was stated in the prospectus that the Regular Medical Examination Association had no interest in the financial result of the schemes. We may leave it to our readers to calculate the financial result of the above-mentioned deductions from subscribers numbering, say, half a million. If the scheme gains the popularity of which we assume it is worthy, the numbers subscribing should be even larger. We shall watch with interest the progress of this association. But we are still of opinion that its prospectuses could be improved if the language employed were clearer.

Mr. LIONEL COLLEDGE, F.R.C.S., will deliver the Semon Lecture of the University of London in the Barnes Hall of the Royal Society of Medicine, 1 Wimpole Street, W.1, on Thursday, November 3rd, at 5 p.m. his subject being "The present position of laryngectomy for cancer of the larynx."

A short and simple ceremony of interest to lovers of Dickens will take place at the British Medical Association House, Tavistock Square, London, on Wednesday next, October 12th, when the Council of the Association and members of the Dickens Fellowship will stand on the site of Tavistock House, in which Dickens lived from 1851 to 1859, and an inscribed stone marking the site, above a portion of the old foundations, will be unveiled.

The following lectures will be delivered next month before the Royal College of Physicians of London: Bradshaw Lecture, November 3rd, by Dr. J. F. Gaskell, on "The pathology of pneumonia"; FitzPatrick Lectures, November 8th and 10th, by Dr. Herbert P. Spencer, on "The history of British midwifery (1650-1800)"; Mitchell Lecture, November 15th, by Dr. P. C. Varrier-Jones, on "Villago settlements and the tuberculous." The lectures will be given at the College, Pall Mall East, at 5 o'clock.

## Opening of the Winter Session.

### THE MEANING AND METHODS OF SUCCESS

Introductory Address given at St George's Hospital,  
October 1st, 1927,

BY

SIR HUMPHRY ROLLESTON, BART, KCB, MD,  
Regius Professor of Physic, University of Cambridge

[After congratulating the winners of scholarships, prizes, and certificates, and mentioning some of the advantages of competing for these rewards of ability and industry, Sir Humphry Rolleston discussed briefly the element of chance in the success or failure of a medical career. Looking back upon the crises of contemporary students and colleagues, it seemed to him that what might appear to the onlooker to be pure luck was often a capacity to make full use of whatever the wheel of fate brought to the feet. He then considered some of the essentials for a right conception of success in medical life, and the various forms which this success might take—the fashionable and financial, the intra-professional, the scientific and intellectual, the humanitarian and personal. The best form of success for the ordinary man to aim at was to preserve his own peace of mind and respect by the consciousness of honest work well done and duty carried out without fear or favour, by making others happier in body and mind, and by freedom from regrets for any action contrary to the golden rule "Do unto others as you would that they should do unto you"]

#### METHODS OF ATTAINING SUCCESS

The arts of success (Sir Humphry Rolleston continued), like the forms of that consummation, are so varied that it would be difficult to mention them all, there is much shrewd advice in Dr. Chesterfield's *Letters to His Son*, by the late Sir William Dalry, on the fundamental questions whether or not medical practice and, if so, which branch of it, is suited to the character, temperament, and attainments of the individual. Some may be admirably fitted to deal with the sick in body or mind, others specially suited to laboratory investigation of the causes of disease, and so privileged to advance medical science, but less adapted to the complex practice of its art in the wards and sickroom. These decisions are, of course, momentous, for to follow the wrong profession is a tragedy and a sure bid for unhappiness and failure. But when what seems to be the right choice has been made, what are the further essentials? Obviously to start with, as in other professions, a thorough knowledge of the science and art—the two Janus-like faces—of medicine, and not only this, but to remain throughout life students, ever on the look out to observe and learn, for there is no trace of finality about medicine, especially in these days, to give up the student life on qualification is not to remain stationary, it is to go back, while others are going forward.

The final examination at the colleges and the universities only qualifies you to enter on a series of further trials and testings—the equivalents of examinations—of which the candidates may be unconscious but which are none the less effective and decisive, by patients, their friends, and professional brethren, medical life, indeed, is just one examination after another. Mental ability alone is not sufficient, though it goes a considerable way towards professional success, and here it may be interesting to quote Thomas Young. In his discussion of the relation between ability and success there is the following dictum: "However inadequate the possession of superior talents alone may be to ensure the confidence of the public, it must be a mistaken opinion, although it has been asserted by persons of no ordinary observation, that a man of great abilities is morally incapable of being a good physician." The explanation of the failure of ability alone is gently but more clearly explained by that great humanist Osler: "A physician may possess the science of Harvey and the art of Sydenham and yet there may be lacking in him those

finer qualities of heart and head which count for so much in life", and more bluntly in Jacob's warning "You may be ever so learned and yet an inefficient doctor," for indeed it is easy to be too bookishly learned and deficient in the wisdom of practical life. Peter Mere Latham, one of the great clinical physicians a century ago, when our science and art were infinitely less detailed and specialized than now, expressed a view which at first may seem somewhat surprising:

"Knowledge may be an encumbrance as well as a help. Many men know more than they are able to wield. There is a point (I believe) in the acquisition of knowledge (and this point varies infinitely in different individuals) beyond which it more is acquired, the whole mass becomes useless to its possessor. I am acquainted with men who never have done, and never can do anything, because they know too much, and I am acquainted with men possessing comparatively small knowledge so dextrous in its use that they have ridden over the heads of others far, very far, then superior in acquirements."

Though reading maketh a full man, too much may induce mental dyspepsia, breed excessive obedience to authority, and so destroy any originality and independent thought. Read we should, but let it be methodical with discretion, and accompanied by critical analysis and digestion, so that the state of the stuffed Strasbourg goose be not the result. As a practical method of analysis a written abstract made at the time serves a double purpose—not only does it impress the details on the tablets of the mind much more effectively than mechanically underlining the book when sitting in an easy chair, but it is most useful for future revision. It is a common mistake to measure the amount of work by the clock, the real criterion is not the number of hours spent, but the degree of concentration brought to bear on the subject. Concentration produces the greatest effect in the minimum time and is the economical secret of the successful and busy man.

There are, in addition, other factors to be considered, especially the knowledge of men and women, which is so important in the treatment of the sick. Though, like most epigrams, "one-quarter of savoir and three-quarters of savoir-faire make the successful practitioner" may be an exaggeration, there can be no doubt of the value of the personal equation in gaining the confidence of patients, their relations, and professional brethren. A man should, of course, have the requisite professional knowledge, but he must also be able to make full use of his requirements. This necessary personality is not shown by a bedside manner with a suggestion of pompous superiority, it is the result of getting inside the patients' minds so as to think their thoughts, feel their feelings, and thus understand their mentality and anxieties so thoroughly that the medical man is obviously their friend, with their interests so entirely at heart that nothing else counts. This is not an actor's mask, but the outward and visible expression of true charity and forgetfulness of self. I would like to subscribe to the following from an address given by my father in 1874 when distributing the prizes at St Mary's Hospital Medical School:

"I believe that the rule 'put yourself in his place,' based on what modern philosophers call the principle of altruism, but what is found expressed plainly enough in much older language than theirs, is the rule which, if I were confined to the choice of one single guiding maxim to be given to a young doctor just entering upon the responsibilities of practice, I should choose for that maxim. Sympathy is truly called a divine gift, and it does assuredly give a superhuman power. I presuppose, of course, patience in investigation and carefulness in ratiocination, but such is often the obscurity, intricacy, and complexity of a medical problem that in the ultimate resort it is upon intuition rather than upon syllogism that its true solution depends. It is to the man who has the touch of genius that strength of imagination which enables him to put himself in the patient's place and thus do full justice to him, that there 'arise' up light in the darkness." It is for want of all this that 'great men are no' always wise."

It is not enough to regard the patient as a machine out of order and an interesting problem in pathology, the man as well as his malady must be studied in order to be properly treated.

The faculty of inspiring confidence, like the love of children and dogs may be unborn for them undoubtedly are men highly esteemed and of acknowledged ability but whom none of their friends think of employing professionally. A want of appreciation of the patients' state of mind which is naturally focused on their ailments may allow the doctor to discourse on his hobbies and private interests, thereby, of course important for his own well-being but from the patients' point of view his reason d'être is solely to discuss their urgent need. No doubt attempts to distract them from themselves have their place and value but the time for this is after, not before. A full—often it must be admitted, tedious—hearing and consideration of their troubles so as to unburden their minds and ensure complete satisfaction. In doing this there must be calmness without coldness, decision without dogmatism, friendliness but firmness. It may be difficult to steer between saying too little and talking too much, and while avoiding garrulosity there is the temptation to imitate those who by a sententious or somewhat cryptic phrase get out of a difficult situation for the time but seldom satisfy their patients' wants. Honesty and truth are essential but what may at the time seem the whole truth should not always, in the light of human fallibility and his best interests, be communicated to the patient, thus a death sentence given bluntly on what may prove to have been insufficient grounds benefits neither the patient nor the doctor. It is well to remember that a doctor's dictum is not forgotten easily by his audience and so though often pressed for a premature opinion it is wise to refrain from speculative prophecy which of all mistakes is the most gratuitous. In making mistake is inevitably all must it is better to err on the side of optimism than of pessimism. It was said of the late Sir William Osler that 'he never left a sickroom without leaving behind renewed hope.'

The doctor's relation with other medical men (popularly spoken of as medical etiquette or ethics with a thinly disguised dislike and a suspicion of a mysterious trade unionism) is in reality a very simple matter—obedience to the golden rule of treating other colleagues as we would wish them to treat us. In carrying out this elementary principle there is nothing more obvious than total abstinence from adverse criticism of other medical men. To maintain your own opinion is right and proper to depreciate the advocate of a different view not only savours of a weak case but is an act of treachery to a profession the motto of which should be team work. Some rather elementary people seem to have the delusion that by undermining the reputation of others their own will be left standing out in bold relief not realizing that such prominence may be of a kind other than is hoped—namely bad as well as bold and far from advantageous to their interests. Before judging of what another medical man is reported to have done or said it is instructive to bear in mind how rumour may transform your own actions and remarks out of all recognition. The expression of unkind thoughts about another is a further step and so commits the speaker that it has a booming-like effect for whenever they meet he pays the embarrassing penalty of discomfort and realizes that "evil communications corrupt good manners."

#### IMPORTANCE OF GOOD HEALTH

Almost as important as common sense and a sympathetic and healthy mind are good health and physique to withstand the strain of hard continuous work. To avoid illness is no easy matter among the numerous exposures to infection in times of epidemic disease especially when overworked. Doctors should not only advise but in their own interests set a practical example in personal hygiene, proper recreation, exercise, and holidays in spite of the numerous difficulties that surround them. From influenza, headache, and dyspepsia born of irregular and hasty meals a man may become irregular, forgetful and deficient in the qualities which make for his success with his patients. The habit of keeping fit should be maintained during student life by combining as the best men so often do, nicely organized work with active games, thus gaining,

in addition to professional equipment, experience and an unimpeachable bearing in the give and take of competition and the term work of later life. On the other hand, great things have been accomplished by medical men crippled or physically handicapped in one way or another, incapacity in one respect may, by compensation and concentration, result in a high degree of excellence in another direction, the bodily weak may become a mental giant and those ill adapted for success on general lines may, by intensive study in a narrower sphere, become specialists of eminence.

Terence's line "Homo sum, humani nihil a me alienum puto" applies most certainly to our humanitarian calling but although wide culture literary activities and hobbies are good for the soul, these are for private use and not for parade. There is widespread belief often no doubt erroneous, that a man cannot excel in more than one line and so when a doctor is known, for example as a writer of verses most people are inclined to consider him too good a poet to be their common-sense guide, philosopher, and friend in unromantic medical matters.

A method of attaining success, though it may seem rather negative and involve some repetition is to avoid the conspicuous causes of failure such as mental idleness, unbusiness-like habits, forgetfulness, unpunctuality, habitual discourtesy, drug addiction and intemperance. Against the last two rather blatant vices a warning may seem quite superfluous but unfortunately not a few able men, already in good positions and reaping the harvest, have become shipwrecked on these vulgar rocks. No doubt there are often extenuating circumstances such as anxiety to keep going when ill laid down, and exhausted, recurrent private misfortune and acute mental distress, but the cause does not concern the public who in any event would not be inclined to excuse the results on that score.

## THE DOCTOR'S HIGH CALLING

Introductory Address at the London School of Medicine for Women

BY

R. G. HOCARTH CBE FRCS, JLD

Senior Surgeon General Hospital, Nottingham Past President of the British Medical Association

I SHOULD like to begin with a brief reference to the London School of Medicine for Women itself. May I not say without presumption that a pioneer educational institution which has survived the strains and stresses of fifty years is bound to have acquired an established reputation? It either stands high or low in the general esteem. It has either made good or it has failed to rise above mediocrity. Well there is no doubt about the status of your school, which in conjunction with the Royal Free Hospital, holds its own in the best company among the medical schools of the British Empire. It is indeed an infant compared with Barts or with Queens which have their traditions of centuries. But after all when we talk about traditions in connexion with medical schools let us remember that their best traditions are scarcely older than the still recent days of Simpson and Lister, and that the London School of Medicine for Women was born amidst the epoch-making discoveries which marked the Renaissance period of British medicine. So it was under a lucky star that your pioneers burst their way through all the obstacles and vindicated the abstract right of women to enter the medical profession by proving themselves apt learners and practitioners of the art of healing.

#### FIGHT OF WOMEN TO PRACTISE MEDICINE

The root of the opposition I suppose was sex prejudice, strengthened by apprehensions of intensified competition. Not that I dislike strong prejudices, either in men or women. They are often the very salt of life. But we must not hug them too long or too close, and, above all, we must be ready to recognize when a case is really proved.

I only recall this now senescent controversy because,

after all, it was the *causa causans* of the foundation of this school, and without existing the slightest aspersion on the system of co-education prevailing in some other medical schools this great teaching school for women students alone is a proud and happy achievement. There are, indeed, some whose zeal for the equality of the sexes disdains any recognition within the profession of the differences of sex. That may be good logic, but we do not live by logic alone, and I prefer either the masculine or the feminine to the neuter gender. It is no use pretending that men are not men, and that women are not women. And the more I think of it, the more I am appalled at the waste that the world for so long has made of its women—the squandering of their rare qualities of mind and heart, the neglect of their immense capacity for service to humanity. Sex equality had to be successed when sex equality was denied, but in the future the debate should rather be as to what men can do best and what women can do best, apart from the huge common field of endeavour which is open to both. It is division of function, according to special capacity, which makes for good organization and efficient service. The widening ranges of the special diseases of women and the special ailments of children seem to belong naturally to women. But we may be sure that these divisions will not be settled by reason alone. The idiosyncrasies, the instincts, the jealousies of human nature are no less powerful arbiters.

#### ADVICE TO NEW STUDENTS

And now let me turn to those among you who are newcomers to these halls. You have made your crucial choice of a career, and I congratulate you upon having chosen Medicine. What Wordsworth in his sonnet to Byron, the painter, said of creative art is no less true of the art of healing: "High is our calling, Friend!" And not only high, but hard. You will find no soft options in the study of medicine, if you have entered here with a desire, not merely to qualify, but to excel, and to earn with your fees the goodwill and gratitude of your patients.

Your new studies will naturally engross the greater part of your time, and those who come quite fresh to science may not have much leisure for other subjects. I would urge you not to neglect altogether those studies which still bear the resonant title of "Studia Humaniora," to distinguish them alike from divine theology and the mundanities of law and mathematics. An exclusively scientific training often leaves something to be desired in the way of mellowness and ripeness, if I may so express it, and the professional man or woman of to-day suffers serious handicaps unless his or her mind is well cultured, well garnished, and sensitive to the impression of what the Greeks called "the beautiful." Do not disperse your energies too widely, but at all hazards avoid narrowness. Most of you, presumably, look forward to general practice rather than to the cloistered specialization of the laboratory. Therefore, read widely of the best. Your medical textbooks contain the rather rudimentary knowledge indispensable for the satisfaction of examiners, but they are markedly deficient in the attractive graces, the uplift, the freshness, and the inspiration that you will find in the best poets, essayists, and novelists. It is not enough for the woman doctor to be distinguished in the street by her spectacles, by her shoes, or by the attractive ease in which she carries her instruments. Apart from her professional skill, she should be known by her intellect, by her judgement and by her common sense. Mental gifts are not sufficient, though it goes a considerable way of approaching professional success, and here it may be interposed the warning of Thomas Young. In his discussion of the relation of talent to ability and success there is the following dictum: "It is never inadequate the possession of superior talents alone; your be to ensure the confidence of the public, it must be not mistaken opinion, although it has been asserted by persons of no ordinary observation, that a man of great abilities is morally incapable of being a good physician." The explanation of the failure of ability alone is gently but more clearly explained by that great humanist Osler: "A physician may possess the science of Harvey and the art of Sydenham and yet there may be lacking in him those

education is still enshrouded in that briefest, most searching, and most comprehensive of all the aphorisms, "And thyself."

Passing from these general observations, I wish specially to congratulate you on the golden moment at which you begin your study of medicine. Though in one sense the young people of each succeeding generation are necessarily the heirs of all the ages, you are exceptionally fortunate to be then inheritors now. The only time, perhaps, when the prospects of those entering the profession in the spirit of scientific adventure or with a real enthusiasm for the welfare of their fellows were in any degree comparable with the present was in the early days of Greek culture, when that "divine old man," as he has been well called, the Father of Medicine, Hippocrates of Cos, first disentangled medicine from priestcraft. He first started the medical profession on its separate individual course, with a set of ethical commandments which, after nearly twenty-four centuries, still find as general acceptance as though they had been dictated in thunder and graven in stone. Medicine was then launched under the finest auspices and with the brightest hopes, and mankind never suffered a more grievous calamity than when the new science drifted into the shoals and quicksands from which it was only effectually rescued in recent times. Medicine, returning once more to Nature, rejecting all methods save that of observation, and all interpretation save that of strict causation by natural causes, has now gloriously renewed itself. Sure of its direction, it looks forward with great confidence to an ultimate control—if the word be not too strong—of disease, though not perhaps of natural death, and to an ultimate penetration to the very springs of life and the fount of being.

#### THE CONFIDENCE REPOSED IN THE PROFESSION

The medical profession, moreover, possesses, to a degree hitherto unknown, the general confidence of mankind. Men and women in all ages have run with anxious fears to the doctor in the hour of trouble, because no Stoic doctrine has ever persuaded shrinking flesh and blood to be reconciled to pain. Yet the keenest wits were never deceived by the professional cloak of mystery with which the doctor shrouded himself from too close a scrutiny and which he dared not put off in the public eye. The reason of so marked a change from a credulous incredulity to implicit confidence is to be found in two words—scientific method.

The Temple of Healing has been rebuilt from its foundations. The fountains of pure water have been cleared from the rubbish of centuries, and through its porticoes and halls blows the fresh clean air of free inquiry. Scientists have, indeed, been driven to invent a jargon of their own, because they need such a bewildering multitude of new words with exact and precise meaning, but there is still only one set of scientific principles, and even in the labyrinthine complexity of modern medicine there is a grand and austere simplicity. The world may be able to afford the luxury of several religions, it can only afford one Science of Medicine, and the unscientific systems which survive in the Far East in their old association with religious ritual belong to another and a different category. Even if we have not cast off all our inherited errors, at least we are now emancipated from the delusory theories on which the world was doctored for centuries. Observation and experiment are the only high road to an exact science, and it was early discovered that "experiment is slippery and judgement hard."

This is the age of scientific adventure, and I should like to remind you of what Sir Isaac Newton said of his own supreme discovery of the law of gravitation. He compared himself to a child playing on the seashore who had had the good fortune to find a prettier and more polished pebble than his fellows, but he added that he had not so much as launched his boat on the broad ocean which called for more venturesome to the discovery of continents still unknown. Such pebbles are being found in increasing numbers to-day because there are many searchers, and as science knows better than before where to look. A few prophecies ago we were celebrating the centenary of Lister. Before long the minor centenaries will crowd upon

us so fast that the world will be too busy to give them due observance. Every department of medical science seems to multiply unceasingly, and still there is no hint of end or limit to the new knowledge that may be found in respect of each. It is a perpetual search for causation. There is surely a prophetic vision or the triumphs of scientific medicine in the majestic line of the Roman poet:

*Felix qui potuit rerum cognoscere causas*

"Happy is he," said Virgil, "who can pierce to the causes of things, and so to temple under foot all fear, and into inevitable and the dim of greedy Acheron." The river of death still flows dark and turbid, but the noise of its waters grows less and the Fates have been compelled to abate many of the worst rigours of their dread sentences. In the search for causes Science has found her cures.

We are not all discoverers of course, whether of pebbles or of continents. In medicine as in other professions, the majority belong to the rank and file who do the everyday mending and patching of common humanity. A vast routine of ailment slight and serious runs with the sun its appointed course. Men and women obstinately continue to transgress the laws of health and in spite of daily articles on diet we may count with certainty on the regular commission of those dietetic irregularities which produce then mixed crop of disorders in the human frame. So long as the pleasant vices are apt to be the most numerous, our professional occupation will remain. Indeed, the more people read about health and diet the more they will go-sip about their pains and symptoms, and the more assiduous clients they become. You need have no apprehensions, therefore, of any lack of patients.

#### THE MEDICAL PROFESSION AND THE STATE

Even to-day you may hear the pessimists lament that there are not enough good jobs to go round. But do not allow such dismal forebodings to depress your natural enthusiasm. Whatever mediocrity may say, there is always room for conspicuous merit at the top, even if at times the scramble is intense and the waiting tedious. In no profession I believe, is the percentage so high as in the medical of those who make a fair success out of their practice. Some forty years ago Sir James Paget used to point to follow up the careers of a thousand medical students who passed through the medical school at Bristol. He found that of those who actually reached practice 66 per cent made a very fair success of it, meaning by that that they were able to maintain themselves as professional men in adequate style. I feel sure that if a similar investigation were undertaken to-day the percentage would work out even higher, and that it could be shown to have risen in a specially marked degree as a direct result of the National Health Insurance Act, which has proved a good friend not only to those who participate in its benefits, but also to the general practitioner whose work has contributed so largely to its success. The State to-day not merely recognizes, but earnestly realizes its direct responsibility for the health of the people: if only because in ailing people means a discontented and an inefficient people and a constant drain without return upon the national expenditure. We suffer in this world for sins committed against the laws of health and decency, the resultant diseases are of human making, and not one is fairly chargeable to Providence. This may seem almost axiomatic to the younger generation, but it was a real discovery to a generation which has not yet wholly passed away. The average doctor of to-day therefore is no longer engaged in purely private practice; a considerable percentage are servants of the State in one form or another. This association of the profession with the State will increase and not diminish, and it opens out an ever widening horizon of honourable and profitable employment.

Consider too the same association of the State with the profession in connexion with the more scientific side of medicine. Research would fare very badly without the State's assistance, inadequate as it is, but those who are ambitious for large incomes had better not take up laboratory or research work, which always reminds me of the swarming activity of bees and ants, narrowly intent on the infinitely little. This work is nevertheless of infinite importance and demands a self-sacrificing devotion from which

few emerge to name and fame. The consolation of the majority must be that all scientific discovery, however humble, contributes to the imposing pyramid which the true master-builders raise. It is only when something spectacular is done, or when something fits with a click and completes the cross-word puzzle which carries the prize that the limelight is thrown on to the research worker. But the work goes on with unhesitating step, and I hope that in spite of what I have said some of you will be lured into the enchanted—if inadequately remunerated—regions which give entrance to the peritralia of Science, remote enough from the everyday world, yet subtly connected, even with what seems most distant and non-related by an endless chain of direct causation.

But no doubt the majority of you will join not the noble army of martyrs to the cause of pure science, but what I may call the goodly fellowship of practising doctors and surgeons. You will find even here scope for the exercise of all the altruism in your composition. The old idea is not yet wholly dispelled that the doctor, unlike the lawyer, ought to be so pleased with his success, if a cure results, that he might reasonably forgo his fee. Perhaps you may feel like that once or maybe twice in your early novitiate, when a doubtful and difficult diagnosis to your great relief, turns out to be correct, but with growing confidence and success you will find new beauties in the text that the labourer is worthy of his hire. I do not believe in the importation of trade union methods into professional life. Whatever is good in trade unionism, we doctors already possess, and the British Medical Association of the working of which I have had invaluable experience during the past year, exists for the protection of the just interests of the doctor. Let me urge you therefore to join the Association as soon as you are qualified for admission. It is the strongest physical bond of union in the profession. Its central administration is kept in constant touch with all its Branches, and through the Branches with each individual member. It is co-extensive with the British Empire in its organization, and while it promotes the sense of fellowship and comradeship, it also possesses a cutting edge which is kept bright, sharp, and aseptic for the occasions when the profession has to defend its rights against encroachment.

#### THE SPIRIT OF FELLOWSHIP

But there is also another and more spiritual bond between doctors, and that is the common spirit which pervades their ranks. I do not wish to pitch the note too high. It would be fantastic to pretend that doctors are immune from the ordinary failings of humanity. But I do think that their calling brings into continual play their finer feelings and instincts, and that doctors are especially sensitive to the call of duty. The public may poke its fun at the Faculty as a Faculty, especially when it is consciously playing its *beau rôle* on the raised dais, but they know that the doctor's fine coat will be off in a trice when there is emergency work to be done and seconds are precious.

The medical art can do much and will do more, and you may be sure that as you grow grey in its service you will see it held in ever increasing honour. I would only counsel you as the specialist extends his sphere on every side, not to be tempted to neglect the close, careful, and anxious method of clinical study which remains no less essential than before. The forward march of science will not abate you from hard work, and the clinical wards of a great hospital and the teaching of an expert clinician are still the indispensable foundation of the doctor's training, without which all the book learning in the world is of small practical use. The apprenticeship may seem long and the course toilsome and arduous, but it has been well surveyed, and the short cuts which look promising are apt to prove fallacious.

I began by quoting to you Wordsworth's famous phrase, "High is our calling, Friend." I will end with the three closing lines from the same sonnet, exhorting you in all earnestness:

Still to be strenuous for the bright reward  
And in the soul admit or no decay  
Great is the glory—for the strife is hard.

## MIDDLESEX HOSPITAL

ADDRESSES BY MR VICTOR BONNEY AND  
LORD JUSTICE SARGANT

THE ninety-third winter session of the Middlesex Hospital Medical School was opened on October 4th with a meeting at the Queen's Hall, when the chair was taken by Mr S G ASHER, chairman of the school council, an address was given by Mr Victor Bonney, and the prizes were distributed by Lord Justice Sargant.

Mr VICTOR BONNEY entitled his address "The paths to the stars." Life, he said, was a battle, and its weapons were a host of higher cerebral cells in the anterior part of the cranial cavity. The number of these cells in each individual probably varied little, their quality varied little also, idiots and geniuses apart, so that the result depended upon the initiative or driving power which put these weapons of the intellect into action. This power might be aspiration or, on a lower plane, ambition, or a just combination of the two. The larger portion of this cerebral army—its infantry, so to speak—must be trained to attain high technical ability, but this by itself rarely secured the highest results. An army consisting solely of infantry would be a very imperfect force. As in warfare other branches of the service were needed, so in the medical profession foresight, tact, judgement, and a faculty of sympathy must come into action. Mere professional excellence by itself would very rarely bring success. While professional knowledge must be the main object, other intellectual attainments must not be overlooked, and the main difficulty was to determine in what proportion the forces should be employed to ensure complete victory. One question to be settled was whether it was better to recruit, train, and put into active service all the intellectual units at once, and so adopt "shock tactics," or make successive drafts on the available raw material and wear the enemy down by cumulative pressure. Success was not merely a matter of getting to the front but of keeping there, though, to be sure, it was far more arduous to get there than to keep there. Of the material honours and distinctions in any profession, it was the first that needed striving for, the second was always more cheaply bought, and when it came to the fifth or sixth the professional collectors of such merely found it necessary to sit still under the flowing stream of favour. While the winning of the first position was the most important, a reserve of force must be left for the holding of this and for the advance to further positions, some mental potentialities also should be conserved for the days of retirement. Innumerable workers had built a marvellous temple of medicine, their example must be emulated, and if another lofty spire could be added by every student, let him at least add one sound stone to the structure by his individual effort. The greatest success of all was to leave one's profession better than one had found it.

Lord Justice SARGANT then presented the scholarships and prizes. He congratulated Middlesex on the great response that had been made to the appeal to the public for the half-million fund for rebuilding, and afterwards offered a few remarks on the position of medicine and surgery in general. He had had occasion to observe during the last few years what an immense amount of work and study was involved in the attainment of a medical degree, for his daughter had lately qualified for practice. It was not merely the great amount of practical work that had to be done, but also the sheer mental discipline to be undergone by those who wished to acquire a knowledge sufficient to enable them to give relief to the public at large. And what had often occurred to him, as it must to all thinking persons, was that after the qualified practitioner had gone through that elaborate and extensive course of study and practice he was met, when he actually entered his profession, by a whole host of persons who attempted to rival him. These were persons who tried to carry on what they called the healing process, whether bodily or mental, without any real and recognized test of their abilities, even in the particular subject-matter with which they professed to deal, and certainly with none of that general medical knowledge which seemed to be essen-

tial to anyone who aspired to exercise the art of healing upon his fellow creatures. Not merely did these persons run the risk of doing actual damage to those whom they affected to treat, but in almost all cases they lulled their patients into a false security, and prevented them from seeking qualified medical aid until, in many instances, the disease had made such progress that the resources of treatment were not adequate to deal with it. It seemed to him that there existed in this country a liberty, in this matter which almost amounted to licence, and which was considerably greater than that prevailing in most Continental countries. Whether there should be some legislative interference, and if so, to what extent, was a very difficult question. In the meantime, at any rate, the qualified medical profession had the protection of its own etiquette, the profession stood together as one body to resist encroachments of that sort. Hard cases had been heard of from time to time, cases boosted by the newspapers regarding someone who had fallen under the ban of the General Medical Council and had not deserved his fate. His own experience was that a great many cases which sounded very adequate on paper, or when one side only had been heard, and the facts had been loosely stated and put forward in an exaggerated way, crumbled to pieces when they came to be adequately examined and tested. In any event he felt that, even if hard cases occurred, there was truth in the maxim that hard cases made bad law, and that it was the general interest of the community which had to be considered, and not the particular hard case. Coming as he did from a profession in which a rigid etiquette was insisted upon, he felt the greatest sympathy with the medical profession when they on their side insisted on an equally rigid and effective etiquette.

Finally, Lord Justice Sargant ventured a remark on the extreme danger to which the medical profession was exposed at the present time with regard to the certification of lunatics. During the last few years there had been a number of cases in which medical men, having acted quite reasonably—having done that which ninety-nine out of a hundred reasonable men would have done in the circumstances—found themselves compelled into the courts and put to the most extraordinary expense and harassment of mind. It seemed to him that as matters stood at present the risks that these men ran were greater than they ought to be called upon to run, and he would rejoice if something were done to relieve them from a responsibility which they felt bound to exercise in individual cases for the protection of the public. No doubt, so far as the financial aspect was concerned, their defence was in many cases undertaken by the medical defence societies, but it seemed to him that those societies really ought not to be called upon to this extent, and that the necessary protection might well be given by law, at least to a greater extent than it was accorded at the present time.

The Dean of the school (Mr Eric Perce Gould) reported that very remarkable success had fallen to Middlesex in this year in the higher examinations. In the last examination for the F.R.C.S. Eng. seven out of the nine Middlesex men who presented themselves were successful. He announced that the Brien Studentship had already been awarded, and the first student had been working in the Ferens Institute for some months, and that a scheme of collaboration had been entered into between the Institute of Biochemistry and the scientific laboratories of Boots Pure Drug Company, Limited.

## WESTMINSTER HOSPITAL

## ADDRESS BY DR AINLEY WALKER

THE ninety-fourth year of the Westminster Hospital Medical School was inaugurated on October 3rd, when Dr E W AINLEY WALKER, dean of the School of Medicine in the University of Oxford, delivered an address on the scientific side of medical training.

Dr Ainley Walker said that followers of medicine had advantages over students in other professions, medical knowledge was always advancing, and work in this field must ever be full of interest. Medicine was both a science

and in art, though in this country it was to the art that the greater attention had been paid, the application of science to it had not, until comparatively recently, received the attention it deserved. But unless the student obtained a thorough knowledge of the principles or the fundamental sciences and some working acquaintance with the ascertained facts in those departments of learning, he would find himself, after ten or twenty years of practice, so completely out of touch as to be unable to apply properly new facts and new methods in the prevention, diagnosis, and treatment of disease. The speaker looked forward to a time when every student of medicine would take a degree in pure science as part of his medical studies, and in the meantime he urged that the training available in the fundamental sciences should not be unduly curtailed or hurried, all the time that could possibly be afforded should be spent on the purely scientific side.

The curriculum of the medical student had lately undergone much modification. With the growth of knowledge and the increase of specialism the subjects with which he must gain some acquaintance had inevitably multiplied and there was some danger that the balance might be upset and the student find himself less able to acquire the sound knowledge of general medicine and surgery necessary to the education of the doctor. A smattering of information about an infinitude of little special subjects must never be mistaken for the education which would fit a man to become a competent physician. It was on the scientific side of medical training that the greatest blots remained, and Dr Anley Walker referred especially to the comparative neglect of pathology and the still graver ignoring of experimental pharmacology. With regard to the former, lately there had been some awakening, though pathology did not yet take that important place in the curriculum of the ordinary medical student to which it was entitled. Experimental pharmacology was still almost unheeded, although the subject was one which to-day offered almost limitless possibilities, a wide field, for instance, had been opened by the increase in knowledge of organic and synthetic chemistry. This was a field which, because of its neglect by the medical faculty, had rapidly become commercialized in certain countries, with results which were highly detrimental to real progress in therapeutics and the treatment of disease. It was hardly too much to say that a new kind of quackery had sprung up, a quackery which was all the more dangerous because it was the doctor rather than the public who was the intended victim. The doctor's attention was continually drawn to much vaunted but ill tried remedies, and puffs and specious advertisements with regard to these invaded his breakfast table.

Dr Anley Walker urged the student whatever might be his subsequent line in medicine, to cultivate for himself as a hobby some special study in which he could take particular interest. He also referred to the pressing need for the fuller development of post-graduate study and the research. The man who had taken a degree in medicine at the beginning of the last century found that post-graduate facilities were generally very few. Many medical practitioners would sooner or later gratefully avail themselves of the opportunity of returning from time to time for the refreshment of their knowledge, the adjustment of their outlook, and the awakening of that renewed activity of mind which resulted from contact with the work and spirit of a teaching hospital. Moreover, post-graduate teaching was in a high degree stimulating and encouraging also to the teacher. Its establishment would lead to redoubled activity in the field of clinical research, a department of medicine in which at the present time somewhat less progress seemed to be made in this country than in others. "Whether in the days to come" (said Dr Anley Walker in conclusion) "you devote yourselves to the practical pursuit of clinical medicine or to the study of one or other of its ancillary sciences, let your aim be high. The lower rungs of the ladder may be crowded, but there is always room at the top. Strive to attain, but in striving still remember that it is the effort, not the attainment, that has lasting value."

After Dr ANOLPHE ABRAHAM had proposed and Mr ARTHUR FRANK had seconded a vote of thanks to the speaker the DEAN (Dr A. S. Woodward) gave some account of the work of the school, laying special stress upon the recent acquisition of a playing field. He mentioned that just under forty students had completed their training and had left the hospital during the last year, the number of students now on the roll was practically the same as a year ago. He also described the post-graduate facilities which had been arranged. Among the prize-winners whose names were announced was Mr P. A. M. SOUTHER, winner of one of the certificates and prizes offered by the British Medical Association for an essay by a fifth year student.

## ROYAL DENTAL HOSPITAL

### ADDRESS BY SIR WALTER FLETCHER

THE annual presentation of scholarships and prizes at the Royal Dental Hospital or London (School of Dental Surgery) on October 4th was made to coincide with the opening of the John Hampton Hale research laboratory, built from funds allocated by the Dental Board and equipped and endowed by Mrs Hale in memory of her husband, who was formerly chairman of the hospital. Both duties were performed by Sir WALTER FLETCHER, F.R.S., who delivered an inaugural address.

Sir Walter Fletcher said that the new laboratory was not only an important addition to the school, but one of the first outward and visible expressions of a striking movement within the dental profession itself. By means of their registration and retention fees the members of the dental profession were contributing to a fund which, on a narrow view, would seem to be damaging to their own interests, for it was used for education, which brought into the field formidable rivals, and for research, which was directed to ensuring that ultimately dental surgeons would have no work to do. In framing its research policy the Dental Board had recognized that, however precise and limited might be the particular professional and utilitarian aims to which dental research was directed, the scientific work by which alone those aims could be properly realized must have complete liberty of range. In the important field of mechanical dentistry the Board had entered into co-operation with the Department of Scientific and Industrial Research, and he believed some really valuable and practical gains had already resulted. He could speak with more direct knowledge of the similar alliance between the Dental Board and the Medical Research Council. There were very few problems in preventive medicine of more importance to the race than those concerning the proper development and preservation of the teeth. Every new gain in knowledge only emphasized the scientific and medical interest of that set of problems. It was the hope of the Medical Research Council that the new laboratory would play a distinguished part in this co-operative scheme of investigation. The value and urgency of this kind of research from the point of view of the citizen and of the nation could not be doubted. Dental imperfections and disease in this country brought, directly and indirectly, a quite colossal volume of discomfort, inefficiency, pain and ugliness while indirectly disorders of the teeth contributed in many ways besides their immediate and direct effects to specific diseases of the body. It was a commonplace now to say that the improvement of the teeth of the nation was one of the most pressing and outstanding problems of preventive medicine. But while everyone recognized the urgency of the research work, by which alone the present ignorance could be removed, it was useless—perhaps worse than useless—to call for quick and easy results from the investigations. Money was necessary to give freedom of opportunity to scientific workers and money invested in research rarely failed to gain a satisfactory rate of interest in the long run—in many cases, indeed, a rate of interest fabulously high. But new knowledge could not be bought like a commercial product. It must be the product of the right man in the right place, and of his unfettered labour. Three hundred years ago

Bishop Hall of Norwich had truly said "There was never good thing easily come by. God sells knowledge for sweat." The true limit to a research programme was fixed, not by the money at its disposal, but by the number of men and women who were fit and available for the enterprise, and those would always be scarce. He pleaded for patience in awaiting results, as well as for orthodoxy of spirit. Nature's clues hardly ever were found in the straight line. The key to some great advance in dental knowledge might be lying implicit in some work that seemed quite alien in kind.

Dental problems had lately been brought, as a consequence of scientific work, into a new atmosphere of hopefulness and interest. The study of attacks made on teeth by particular agents of disease had proved relatively barren. What was needed was not so much better knowledge of the diseases of the teeth as better knowledge of the health of the teeth and the conditions of their natural resistance. Recent work had increasingly brought dental problems into line with those of the general physiology of the body and the science of nutrition. Clear experimental evidence had been forthcoming that the normal architecture of the teeth, like that of the bones, depended to a surprising degree on the right supply and balance of diet at the time of growth. It seemed also that, whether from the intricacy of their structure or for other reasons, the teeth in their formation were even more sensitive to nutritional conditions than other parts of the body. It was by no means unlikely that dental practitioners in the future would perform a wider service to their colleagues in other medical fields in connexion with that new and sensitive index to normality—that is to say, to health—which the teeth in their formation and repair seemed destined to provide. He thought it no rash speculation that the whole medicine of the future lay in the lap of nutritional science.

Mr Norman Bennett, who presided, said that Sir Walter Fletcher had uttered a much needed word on behalf of dental research. He had given full and deserved credit to the Dental Board for supplementing the resources of the Medical Research Council in aiding dental research, but the fact was that dental research had been instituted some few years before the Dental Board came into existence. The Medical Research Council was responsible for that movement, and the principal stimulus in promoting such research came from Sir Walter Fletcher himself.

## ST BARTHOLOMEW'S HOSPITAL

### ANNUAL DINNER

THE annual old students' dinner of St Bartholomew's Hospital was held on October 3rd, in the Great Hall of the hospital. The chairman was Dr H Morley Fletcher, senior physician, and a welcome departure in the proceedings was the limitation of set speeches in order that full opportunity might be afforded for social intercourse.

After the health of the King had been honoured, the toast of "Prosperity to the Medical College of St Bartholomew's Hospital" was proposed by the chairman, who faithfully followed the instructions he said he had received to be brief and bright. Beginning with a reference to the origin of the medical college, which was veiled in antiquity, he mentioned that in 1667 an order had been issued for the formation of a library in the hospital for the use of governors and scholars from the universities. Minutes have been done, in 1840, the shortening of the medical year, suggested by those who wished to liberate the staff in the inefficient to enable them to give relief dinners on record age. And what had often occurred to conversation after all thinking persons, was that after the notice in the *Times* over had gone through that elaborate, under the name of study and practice he was met, wise grandson, entered his profession, by a whole host of wished member attempted to rival him. These were persons who at that time carried on what they called the healing process, with bodily or mental, without any real and recognition in Church, their abilities, even in the particular subject-matter, had, it which they professed to deal, and certainly with Coming that general medical knowledge which seemed to be

to more recent history the chairman referred to the late stride being made in establishing the new surgical block, this would consist of five surgical wards, each with a fully equipped theatre, and would accommodate 250 patients. Every effort was being made to ensure that this addition to an historical hospital should be the finest of its kind in existence. Dr Morley Fletcher referred appreciatively to the work of Miss Mackintosh, who had now retired from being matron of the hospital, her successor, Miss Day, returned to the institution where she had received her training in nursing, and was assured of a very warm welcome. Among the losses sustained by the hospital during the previous twelve months were those caused by the deaths of Dr Clave Shaw, who had been connected with it from 1871 to 1908, Dr T S P Strangeways, who had been junior curator of the museum before his departure to Cambridge, Dr L Phillips, Mr Alban Dorn, and Sir Arthur Shipley. Sir Frederick Andrewes, whose connexion with the hospital had lasted thirty-one years, had retired from the chair of pathology, and regret was expressed also at the departure of Sir Bernard Spilbury. Welcome was extended to three new professors—namely, Mr W le Gros Clark, professor of anatomy, Dr Hamilton Hartridge, F.R.S., professor of physiology, and Dr C H Kell, who had returned to London from Cardiff to occupy the chair of pathology. Sir Berkeley Moynihan had received the distinction of being elected to full studentship of the hospital, a mark of appreciation which had only been awarded in two other instances. Congratulations were offered to Dr Burt White, who had gained the gold medal for obstetrics in the M.D. examination of the University of London. Gratifying progress was being made in the medical school, but its expenses were increasing, and it was hoped that money might be received from outside the hospital for the endowment of the professorial chairs. The chairman added, in conclusion, that, in proposing the toast, he would emphasize the point that "prosperity" denoted the continued production of a very high type of medical practitioner, and the maintenance of the strong spirit of *esprit de corps* for which St Bartholomew's had always been distinguished.

In a short subsequent speech the chairman proposed the health of the distinguished guests, who included Sir John Rose Bradford, the Regius Professors of Medicine from Oxford and Cambridge (both old students of St Bartholomew's), Surgeon Vice-Admiral Gaskell, Medical Director General of the Royal Navy, Air Vice Marshal Munro, Director of Medical Services, Royal Air Force, Lord Stanmore, treasurer of the hospital, and Sir William Lawrence. The health of the chairman was proposed by Sir Charles Gordon-Watson, and was received with much honours. An adjournment was then made to the library, where the proceedings became even less formal and more cordial.

## ST MARY'S HOSPITAL

### ANNUAL DINNER

THE annual dinner of St Mary's Hospital Medical School was held at the Connaught Rooms, London, on Saturday, October 1st, the chair being taken by Dr Wilfred Harris. The guests included Surgeon Vice-Admiral Gaskell, Air Vice Marshal Munro, and the Mayor of Paddington. Proposed the toast of "St Mary's Hospital and Medical School," the chairman contributed some reminiscences of his early days as a student and resident before the Clarence Building was erected. He sketched the progress of the hospital briefly and remarked that the handicap of inadequacy of beds for patients seemed now at last to be in a fair way to be overcome. The recent acquisition of the "rehab site" was, he believed, an outstanding event in the history of St Mary's, it might soon become possible to provide small wards for paying patients, which would not only supply an urgent need but would also be of great value to the clinical and teaching staff. Mr A R Pridmore, chairman of the hospital board, and Dr C M Wilkins, dean of the medical school, responded to this toast. Pridmore, after a tribute to Sir Almoth Wright, president

consider the hospital extension scheme, and expressed the hope that many beds would become available before the end of October. The date for the final completion of the work was April 30th, 1928. The scheme included the provision of two operating theatres, which, thanks to the assistance rendered by Mr Maynard Smith and Professor Pannett, had risen to rank as the best equipped and most convenient in the whole country. Some sixty beds would be added to the hospital complement, bringing the total number of beds to about 350, St Mary's would thus be placed in a far better position as regards treatment than it had ever reached before. Moreover, the "island site" which would pass into the possession of the hospital in November, subject to certain limitations under the Rent Restrictions Act, would enable a great step forward to be taken, particularly with regard to the provision of beds for paying patients. It was estimated that the extensions now approaching completion would cost £50,000, of this some £38,000 had already been raised by the efforts of the hospital secretary without a public appeal, and it was hoped that the balance would be forthcoming before the official ceremony next April. Dr Wilson, confining himself more particularly to the medical school, spoke of its early days, and mentioned that the hospital was attracting an increasing number of students from Oxford and Cambridge. He enumerated the special advantages offered by St Mary's to those who studied there, and mentioned that a high proportion of recent academic successes had been won by members of the Rugby football club, showing that the increasing athletic prowess of the hospital was not interfering with medical study. The health of the chairman was proposed in a witty speech by Mr D C L Fitzwilliams, and Dr Wilfred Harris replied.

## THE BOARD OF CONTROL

### RESEARCH WORK IN MENTAL HOSPITALS

THE sociological and medico-legal aspects of mental disorder have been brought in recent years into such prominence that the scientific aspect has tended to fall into the background, with the result that scarcely sufficient notice has been paid to the steadily increasing amount of research carried on in mental hospitals throughout the country.

For some years now it has been the excellent practice of the Board of Control to publish as part of its annual report an account of this work, consisting of a digest of the annual reports of research departments of every mental hospital in England and Wales. It is embodied in Part II of the annual report of the Board, the publication of which has followed hard on the heels of Part I, of which some account was given last week (p. 606).

The digests occupy forty-four pages, and contain several substantial pieces of research, some of which have already been turned to good account in the treatment of mental disease. Many of these investigations cannot as yet be expected to yield practical results but, by adding to the general fund of knowledge, may at a later date enable positive scientific conceptions to be formulated. So manifold is the nature of mental disorder and so obscure is its etiology that, no matter along what lines research may be prosecuted, conclusions are difficult to attain.

It is natural that the majority of the work summarized should be concerned with general paralysis, as in this disease we have a known cause and a definite pathology but even here we are confronted with innumerable problems. The existence of "neurotropic" strains of the spirochaete declared by some workers to explain the vulnerability of the nervous tissues to this infection is not proved. The histopathological findings still await their definite clinical correlates. The variance of the mental states in general paralysis requires explanation, are they the inevitable outcome of the disease process, or are they the result of the accidental exposure of personal psychological peculiarities? There is also to be sought an explanation of

the differentiation of types, the classic delusional type, the depressed, the "pure" dementing type, and those showing blends of organic and schizophrenic psychoses. Lastly, and of more immediate interest, there are the problems of treatment, of the power of penetration into the nerve cells of chemical compounds, of their mode of action, whether treponemacidal or as adjuvants to tissue resistance, and of the rationale of remissions and the correspondence of serological changes with clinical improvement. Indeed, the problems are endless, and it is with interest that we turn to the results of investigation of this disease. The majority of these investigations are concerned with treatment.

From the West Riding Mental Hospital at Wakefield, of which Professor Shaw Bolton is the medical director, comes a note by Dr J F Smyth on the histopathology of general paralysis. Forty cases were examined, and each was followed clinically and verified *post mortem*. A survey of results shows that spirochaetes were most easily found in fairly rapid subacute cases with a clinical history of grandiose delusions and marked physical signs. In cases where spirochaetes were numerous plasma cell periarteritis was moderate, but where spirochaetes were scanty or absent altogether the periarteritis was gross, thus suggesting that it is a defence reaction to the invasion of spirochaetes. Vascular proliferation, particularly of the large and medium vessels, seemed to be part of a general reaction and not dependent on the presence of spirochaetes. The presence of spirochaetes in the motor cortex did not appear to bear any relation to the incidence of seizures. The important feature in these cases was the vascular process.

As regards the various forms of treatment, malarial therapy has received the most attention. Dr Golla, director of the pathological laboratory at the Maudsley Hospital, reports that it is followed by a greater number of remissions and a smaller death rate than occur in untreated cases. Complete remissions occur in about one-third of the cases, but in a much greater proportion in only cases with a history of the disease for less than eighteen months are treated.

From the County Mental Hospital, Whittingham, come observations made during the treatment of general paralysis by the "Whittingham strain" of artificially induced malaria. This strain has been transmitted by direct subcutaneous inoculation through twenty-six cultural generations comprising over 180 inoculations. The conclusion previously reached was in no way impaired—namely, that the attacks of malaria were not becoming more virulent, from the study of 10,000 blood films it appeared that the morphology of the parasite remained unaltered.

A method of treatment somewhat similar to that by malaria is described by Dr J H MacKenzie of Birmingham City Mental Hospital—the material used being T A B vaccine (Burroughs Wellcome and Co.) administered intravenously in daily doses for ten days with intervals between for the administration of A B in four weekly doses of 0.65 gram, three ten-day courses of pyrexial treatment being aimed at in each case. Severe rigors were constantly obtained and temperatures up to 106° were recorded. Vomiting and diarrhoea were prominent features during the early stages, and herpes occurred in a large percentage of cases. No permanent ill effects were noted, and in many cases considerable general physical improvement resulted without, however any constant alteration in neurological signs or serological findings in the blood or cerebro-spinal fluid.

From the Cardiff City Mental Hospital come the reports of numerous investigations. Dr Goodall and Dr Scholberg have been studying the distribution of the nitrogenous compounds in the plasma and cerebro-spinal fluid in mental disease, and Dr Stenford has been investigating the nitrogen constituents of the blood plasma, the cerebro-spinal fluid and the urine. The nitrogenous constituents of the cerebro-spinal fluid have never been systematically studied, and there is every likelihood that this work may not only bring to light new diagnostic tests for disease but that it will help to elucidate the functions of that fluid. Investigations reported from other mental hospitals

include studies of cases of pellagra, a disease now more frequently identified than formerly, of Huntington's chorea, and of epidemic encephalitis and its mental sequelae.

Altogether there is much promise in the research work which the Board of Control has here collected. We need not refer to it in detail. Necessarily much time has to be spent in routine laboratory investigations, and especially into the nature of asylum dysentery and of allied infections, where these are prevalent. But the amount of investigation into mental disease is gradually growing. The Board constantly urges that every mental hospital should have its own well equipped laboratory and that every encouragement should be given to medical officers to pursue research into the nature of mental disease. It is a matter for congratulation that the central authority, which has shown itself so constantly aware of the necessity for sociological and legal improvements, should be zealous also in the encouragement of the research workers throughout the mental hospitals in the country.

## MEDICAL DEFENCE UNION

### Annual Report

THE annual report of the Medical Defence Union, presented at the annual meeting held at Harrogate on September 24th, an account of which was published in our last issue (p. 608), states that the number of new members elected in 1926 was 1,260, a figure exceeded on only two previous occasions. The total membership now stands at 14,418, and includes 1,138 women.

The report refers to a case in which the Union was called upon to defend two of its members against whom damages were claimed by the same plaintiff for wrongful certification under the Lunacy Act. A successful application was made to have the action stayed under Section 330 of the Act on the plea that there was no reasonable ground for alleging want of good faith or reasonable care. The plaintiff, however, went to the Court of Appeal, which held that the affidavits of his expert witnesses, alleging a lack of reasonable care and in one instance bad faith, could not be ignored, and therefore the order for the stay of proceedings was set aside. The case went to trial, but was stopped before the defendants' case was concluded, and a verdict returned for the defendants. The report points out that the decision of the Court of Appeal that the case must go to trial was based solely on the affidavits made by three medical practitioners, one of whom did not see the plaintiff until nine months after the certification in respect of which negligence was alleged and the other two not until two years later. "The views expressed in these affidavits, completely negatived subsequently by the verdict, prevented a stay of proceedings at an early stage, deprived the defendants of the protection which the law is intended to give them, and in addition cost the Union nearly £5,000." The solicitors to the Union (Messrs. Hempsen) add that "These deponents made no inquiries to ascertain the plaintiff's medical history from the numerous medical men under whose care he had been, but expressed their opinion as to his mental state some years previously on the word of the patient, uncorroborated by any skilled or unbiased person."

One minor matter mentioned in the report is an interesting point touching midwives' cases. A practitioner had been asked to attend a woman in confinement, but declined to do so, and at her request gave the name of the nearest midwife. A week after the confinement the midwife sent for the practitioner under the rules of the Central Midwives Board, and he paid three visits. The local supervising authority then refused to pay the practitioner's fee on the ground that it was not empowered to pay the fee when a practitioner had been called to a case by a midwife whom he had himself recommended. The matter was referred to the Ministry of Health for decision, and eventually the fee was paid. The warning is to the need for advising patients with injury to a bone or joint to undergo an x-ray examination. It is repeated, it is stated that the council has to deal at every meeting with claims against members who have neglected to take such a precaution.

The report adds that many cases of unqualified practice and false assumptions of medical titles have been investigated

during the year, but in no case has the evidence available made it possible for the council to authorize proceedings against the offenders. This is due solely to the present inadequacy of the law. The cases handed over to the solicitors during the year numbered 91, of which 6 were libel or slander actions, prosecuted or defended, 32 were defences against allegations of malpractice, and the remainder chiefly arbitrations between members of the profession. The balance sheet of the Union shows assets amounting to £31,000, and apart from its own funds the Union has effected an underwriting policy with a first class insurance company to cover claims over a certain limit.

## England and Wales.

### MEMORIAL TO PROFESSOR ADRIAN STOKES

THE personal friends and colleagues of the late Professor Adrian Stokes (of whom a full memoir appeared in our last issue) have decided to establish a permanent memorial to him. The precise character of the memorial will depend upon the funds which become available, but the object will be to endow medical research in some form. His friends are convinced that the establishment of a Stokes Memorial Fellowship or Studentship is the only type of memorial which he himself would have approved. The funds will be controlled by Guy's Hospital Medical School, and subscriptions should be sent to the Dean, Guy's Hospital Medical School, London, S E 1.

### HOSPITAL EXTENSIONS IN STAFFORDSHIRE

H R H Prince Henry, on October 1st, opened extensions of the North Staffordshire Royal Infirmary and laid the foundation stone of the new Haywood and Tunstall War Memorial Hospital. The new buildings of the infirmary have cost about £180,000, of which £130,000 has already been raised. At the opening ceremony Lord Lichfield stated that the infirmary, which was founded in 1766, was the first hospital established in the Midlands. A new ward block has now been erected and provision is being made for the construction of additional wards on the first and second floors, at a moderate cost, should occasion arise. The windows throughout this building reach to the ceiling and open to their full extent. In unfavourable weather fresh air can be drawn into the wards and removed by means of a fan in a tower in the roof. Two electric lifts and a handsome staircase connect the various floors. The nurses' home has been enlarged to accommodate an additional sixty-five nurses, and a room is provided for instruction in the preparation of meals for patients. The staff department has been reorganized and better arrangements have been made for the protection of operators. Other additions include a new laundry and boiler house, work shops, kitchen, and dining-room, and a new mortuary. Prince Henry referred to the fact that the foundation stone of the existing infirmary buildings was laid sixty-one years ago by the then Prince of Wales, and commented on the great advance in medical knowledge since that time. The foundation stone of the present extension was laid by the King in June, 1925. It is hoped that the new Haywood and Tunstall War Memorial Hospital, which will cost about £35,000, and contain sixty-five beds, will be adequate for the needs of Burslem and Tunstall. For many years the accommodation at the existing Haywood Hospital has been too restricted for this populous area.

### THE PAPWORTH VILLAGE SETTLEMENT

Reporting on the work in 1926 of the Papworth Village Settlement near Cambridge, Dr P C Varrier-Jones the medical director, draws attention to the fact that eleven years' experience at this institution for tuberculous patients has shown that the children of infected patients do not suffer from segregation at such a colony, but actually receive benefit. No child has contracted tuberculosis at the settlement, and support is available for the contention that the family, rather than the tuberculous individual, is the unit to be treated in any scheme for dealing with this disease. Interesting details of the work carried on in the village and workshops are presented in the report, with numerous

illustrations. A sick fund started by ex-patients has been able to carry forward a substantial balance on the two years of its existence which is contrary to what might have been expected. A village hall is in process of construction and the Wesleyan Chapel is now nearly complete. A note on this Village Settlement appeared in the *JOURNAL* (April 9th, 1927, p. 656), and the important question of employment for the tuberculous, including a reference to the valuable work carried out at Papworth, was discussed at some length on July 3rd, 1926 (p. 20).

## Scotland.

### ROYAL INFIRMARY, EDINBURGH

At a meeting of the managers of the Royal Infirmary, Edinburgh, on September 26th, Dr R. A. Fleming, who had relinquished the position of physician to the institution, was appointed consulting physician and the managers put on record their regret at the loss of his services, which had lasted some thirty years, first as pathologist, then as assistant physician (1900), and afterwards as physician (1915). At the same meeting various legacies and donations to the hospital were announced, including a sum of £1,000 from Mr Thomas H. Whitehead for the purpose of naming a "Robert Burns" bed in the hospital.

### HEALTH CONGRESS AT INVERNESS

The fifty-third annual congress of the Royal Sanitary Association of Scotland was held at Inverness on September 28th. Dr John R. Currie, M.D., professor of public health in the University of Glasgow, delivered a public lecture on the subject of pestilence. The theme, he said, had at the present day lost much of its terror in Britain, and when one traced the course of the plague down to the present day its disappearance from this country was found to be due, not to any definite measures taken for its control, but to the social and unconsciously hygienic uplift which marked the transition from the Middle Ages to modern times. Leprosy had retired before the same good influences. The movement which undermined the position of typhus and typhoid fevers long before there was any accurate knowledge of their cause was an effort aimed at the conditions which attended these diseases. On the other hand, small-pox, measles, and influenza had been practically unaffected by sanitary improvement, and modern medicine had stepped in with a type of protective agency of which vaccination for small-pox and immunization against diphtheria and scarlet fever were outstanding examples. As regarded this hygienic uplift, one of the recent developments was the growing cult of the open air. This had been greatly extended by field sports, athletics, and outdoor games, which were shared by increasing numbers in every walk of life. A moor or a golf course was a safer place when infection was prevalent than a theatre or picture-house. The cult of the open air had derived a great impetus from the institution of summer time, which kept people out of doors and added an hour to the possibility of life in the open air. The recent appeal by the Duke of York for the provision of public playing-fields was a further recognition of this cult, and these would be great improvers of physique and moral. With regard to the need for better houses, it should be remembered that infection did not go through partitions, and therefore for houses of equal floor space three rooms were better than two and four better than three. With regard to infections of more modern notoriety like poliomyelitis and encephalitis lethargica, the lecturer thought there was room for an uplift among members of public health committees, who by combination and arrangement or hospital service, could place specialized treatment within the reach of those who required it.

The congress was continued on Friday, September 30th, when Dr A. S. M. Macgregor, medical officer of health for Glasgow, president of the congress, delivered his presidential address. He said that there were daily indications

that resistance to the advance of hygiene was weakening in every direction. Somewhat haphazard legislation had been evident in the last few years, induced by the need for keeping pace with advances in scientific knowledge, and there was a growing acceptance by the public of the laws of elementary hygiene and an improvement in many of their habits and customs. Public health to-day wore quite a different aspect from that it had fifty years ago. There was general agreement that the time for the unification of the health services was ripe. The essential of successful administration of health services was now seen to lie in the direction of interdependence rather than of independence. Administration in the more recent aspects of child welfare, school medical inspection, housing, and health propaganda was having a slow but sure educative effect. A result of this was the remarkable increase in the expectation of life which had occurred within the past fifty years. Between 1870 and 1921 seventeen years had been added in Glasgow. He thought that in this a large share should be allotted to increasingly high standards in general medical practice. To those whose business it was to study the factors which influenced the public health, nothing had been more remarkable than the reduction in the average consumption of alcohol.

A discussion on the future of local authority hospital services was introduced by Dr J. Parlano Kinloch, medical officer of health for Aberdeen, who said that impending reform of the Poor Law medical services had given a fresh stimulus to these discussions, but there was also a general consensus of opinion that the existing hospital situation was in some respects unsatisfactory. He had come to the conclusion that the future development of the hospital services of local authorities was to be found within a regional hospital system consisting of four systems grouped round the four medical teaching schools of Scotland. It was hazardous, he thought, to forecast in any detail the ultimate regional hospital organization that would emerge, but the affiliation of all bodies at present providing health services would appear to be the logical outcome. It was not, however, desirable that this unification should be attained by any revolutionary process, but rather by the gradual growth of co-ordination.

A discussion on the administration of the Tuberculosis Order of 1925 from the public health point of view was opened by Mr Hugh Begg, county and district veterinary inspector of Lanarkshire. The present Order, he said, should be strictly enforced throughout the country, and the Ministry of Health should give increased encouragement and financial assistance to the establishment of additional tubercle-free herds. Later on the Tuberculosis Order should be amplified to give powers for the slaughtering of all old cows unless they were certified to have recently stood the tuberculin tests. Dr Gerald Leighton, medical officer to the Scottish Board of Health, referred to the improvement of milk supplied in recent times, and expressed regret that some local authorities were slow to realize their responsibilities in regard to the Tuberculosis Order.

### DUNFERMLINE AND WEST FIFE HOSPITAL

A scheme has been on foot for some time to extend the Dunfermline and West Fife Hospital at a cost of about £50,000, and the first step was taken on September 2nd when Lady Veronica Bruce and Mrs. Andrew Carnegie cut the first sod on the site of the wards to be erected. The hospital was opened in 1894 as the Dunfermline Cottage Hospital, and since then has been enlarged on two occasions. The extension at present proposed will include two wards to accommodate forty-two patients, a new operating theatre, an out-patient department with out-patient operating theatre, bacteriological and pathological laboratory, and an x-ray room and installation. After the ceremony of cutting the first sod, Dr Allan Tulke, senior medical officer of the hospital, presented to Lady Veronica Bruce and Mrs. Andrew Carnegie miniature gold spades inscribed to commemorate the occasion. The ceremony was also made an opportunity for holding a "Students' Day" in aid of the extension fund, at which over £100 was collected in Dunfermline.

## Correspondence.

## THE ETIOLOGY OF EPIDEMIC ENCEPHALITIS

SIR,—It was hardly to be expected that my brief review of the experimental work on epidemic encephalitis should pass without criticism. It is obviously a subject on which different opinions may be held, even by those who have had time to digest the enormous mass of literature dealing with it. I am, however, sorry that I seem to have been unfair to Professor McIntosh's experiments on the transmission of the disease to animals. I passed over this work in a sentence, including it, perhaps unjustly, with that of Locwy and Strauss and of Kling and his associates. I was influenced in this by earlier reviewers and by the similarity of the cage-to-cage infection in his monkeys with the epizootics associated with the *Encephalitozoon cuniculi* which had occurred in other laboratories. I had not seen his reply to Flexner's review.

There can be little doubt that he infected two monkeys out of four with an encephalitic virus. From the first infected monkey he also inoculated three rabbits, of which one died and showed histological evidence of encephalitis, another became ill but recovered, and the third remained well. I have been unable to find any paper of his dealing with further experiments on rabbits, and therefore do not understand his reference to 70 per cent positive results on these animals. His remarks on the dissimilarity of the lesions in transmitted encephalitis with those associated with the *Encephalitozoon cuniculi* are counterbalanced by Dr Woodcock's letter, in which the thesis is advanced that the *Encephalitozoon cuniculi* is a reaction of the rabbit's tissues to a multiplicity of viruses, "including that of epidemic encephalitis." Although it is quite likely that the bodies to which this name has been given are merely one stage of a parasite which is invisible in other stages, it appears in the highest degree improbable that so distinctive a phenomenon should be common both to an epizootic disease of rabbits and to transmitted encephalitis lethargica.

I did not make it clear in my paper that the "encephalitozoon" infection might be associated with nervous symptoms, as it was in Kling's experiments. This no doubt depends on the virulence of the virus. That the "encephalitozoon" bodies were found only in his inoculated animals, and not in the controls, proves nothing except that the conditions for cage-to-cage infection were wanting in his animal house. It is, of course, possible that Kling has transmitted either herpes virus or other encephalitic virus along with the *Encephalitozoon cuniculi*. My point was that the presence of the "encephalitozoon" in the brains of a large proportion of his inoculated animals greatly reduces the value of his results—I am, etc.,

J G GREENFIELD

Pathological Laboratory, National Hospital,  
Queen Square, W C, Oct 3rd

SIR,—Dr Greenfield's remarks at the Annual Meeting at Edinburgh (BRITISH MEDICAL JOURNAL, September 24th, p 535) on the pathology of this condition were certainly as controversial as a study of the reports of other observers would appear to warrant. The present position as to the etiological value of experimental encephalitis is not easily estimated and cannot certainly be dismissed lightly.

Few observers have succeeded in isolating and transmitting a virus similar to that of Leviditz, whilst he himself claims that with his virus an encephalitis can be produced even by genital inoculation in the same manner as syphilis. It is generally agreed that a "spontaneous" encephalitis can occur in rabbits, but this epizootic type appears to be due to a sporozoon. It gives rise to renal lesions and it cannot be transmitted directly to other rabbits. McCartney, who has investigated this condition fully, failed to transmit it.

I should like to draw attention to the work of Szamanowski and Zilberlast-Zind,<sup>2</sup> who used on rabbits a number of viruses obtained from different sources—namely,

the virus of idiopathic herpes and viruses obtained from infective cerebro-spinal fluid, nasopharyngeal washing, and brain emulsions of human beings dead from epidemic encephalitis. An encephalitis, either acute or chronic, was the almost constant result of these experiments, and the rabbits showed no renal changes post mortem, and the condition could be transmitted from rabbit to rabbit. In other words, the encephalitis produced was not similar to the epizootic encephalitis of McCartney, but resembled that which has occurred in man during the last decade.

It is interesting to note that many of these animals infected with what one might call for the purposes of argument "human" encephalitis showed marked vestibular phenomena, the importance of which I have had the opportunity of describing elsewhere<sup>3</sup> when occurring clinically in man—I am, etc.,

Oldham, Oct 1st

RICHARD I POSTON, M D

## MOBILE LABORATORIES IN THE WAR

SIR,—With reference to the obituary notice of the late Professor Adrian Stokes, which appears in your issue of to-day, several statements appear therein which unfortunately have no historical basis as to fact, and, in justice both to the living and the dead, I think should be corrected.

With regard to mobile laboratories, the construction of the first of these was undertaken by the Medical Department of the War Office directly after the outbreak of war in August, 1914. In that year it functioned in battle zones north of the Lys, and thereafter was entirely responsible for the bacteriological investigations in Belgium of all cases in the outbreak of typhoid fever among the Belgian civilian inhabitants in the winter of 1914-15 in the zone occupied by the British Second Army and also by the French army on our left flank. This laboratory was in charge of a territorial officer who had been seconded from the 3rd City of London Field Ambulance, and, later, was appointed to act as my sanitary officer, and was given special authority to carry out all necessary measures for controlling and suppressing the epidemic by the Belgian Ministry of the Interior. This epidemic was considered to have terminated by the beginning of June, 1915.

The second laboratory—a converted motor caravan—was furnished by the Lister Institute, who, within a week of the declaration of war, had made a collective offer of its workers for service under the War Office, followed by an offer of a mobile laboratory, the latter being immediately accepted. This laboratory was in charge of Major S D Rowland and proceeded to France, being stationed at General Headquarters at St Omer, where it remained until its transfer to the Second Army, when it was attached to No 10 Casualty Clearing Station at Rem. Siding and opened out for work early in July, 1915. It was upon the occasion of this transfer that Adrian Stokes first came to the Second Army, he being attached to Major Rowland's mobile laboratory and acting as his assistant until 1916, when Rowland was transferred at his own request to Etampes to investigate cerebro-spinal fever, subsequently contracting the disease there, from which he died. My appreciation of Stokes's services and ability was such that I had no hesitation in securing his appointment as commanding officer to succeed Rowland, this being in fact Stokes's first command of a mobile laboratory.

By this time some five mobile laboratories had been connected with the Second Army, and I would here say that the repeated successful detection and isolation of typhoid (and other) carriers was regarded by all of them without exception as an ordinary laboratory achievement.

Owing to their increasing numbers, it became necessary in 1915 to number serially the mobile laboratories. In that year the first War Office built laboratory became known as No 4 Mobile (Hygiene) Laboratory and the Lister Institute converted caravan as No 1 Mobile (Bacteriological) Laboratory.

In justice to all concerned I would like to make it clear beyond all doubt that Stokes was not transferred to the Second Army until after the termination of the epidemic.

<sup>2</sup> Brain, 1923, 46, 49<sup>3</sup> Brain, 1926, 49, 482.

He took no part, officially or otherwise, in the operations conducted by the medical service of the Second Army under my direction for dealing with the typhoid epidemic amongst the civil population of Belgium which occurred in the winter of 1914-15.

The history of this epidemic remains to be written, it is the story of a grave and widespread outbreak—numbering thousands of cases—amongst the civil population of a foreign country in the occupation of Allied (and British) troops in an intensely active war zone, in which British medical officers were given the honour and the responsibility for conducting the whole of the operations necessary for coping with the disease. They did so successfully, and I would like to take this opportunity to make an appeal to all in possession of relevant documents and records (whether copies or originals) to communicate with me in order that some organization might be set up for duly recording its history and noting its clinical and epidemiological lessons—I am, etc.,

ROBERT PORTER

Major General (Ret.) formerly Director of  
Medical Services Second Army, B.E.F.

27 The Avenue  
Beaconsfield, Kent,  
Oct. 1st

### HOSPITAL POLICY

SIR,—The Poor Law medical service has been hitherto so comparatively marvellous that perhaps you will allow one who has had experience of several voluntary hospitals, and who is now on the staff of one of the most progressive of the Poor Law hospitals, to make a few points. The reason for this silence is not far to seek. The Poor Law medical service has had no such traditions or academic standing as those of the voluntary hospitals, and has suffered from that inertia inseparable from a whole-time service ostensibly controlled by a lay committee, coupled with the fact that only recently have the cases treated in these hospitals become similar to those in voluntary hospitals.

After reading and appreciating highly the report of papers and discussion at the Edinburgh Annual Meeting on "The future relation of municipalities to the voluntary hospitals" (October 1st, p. 575), it seems to me that a few further scarcely debatable points might be worth mentioning.

1. The actual governing body of any hospital voluntary or municipal, is, and must be, the medical staff. The voluntary hospitals have long recognized this, and the results speak for themselves. The Poor Law system has suffered from this authority being vested in only one medical man, fortunately of high capabilities as a rule, but this, of course, will change during its evolution. But in all cases (voluntary, Poor Law, or municipal services) the ostensible governing body—the lay committee, which has the last say—is composed of enthusiasm and well-meaning amateurs, whose hobby it is to devote their spare energies to such excellent work. Such a vital service as ours, however, cannot be run as a hobby. It behoves, therefore, the medical men of all services to take a keen interest in this question.

2. Mr Herbert Eason refers to the difficulty of giving chapter and verse in support of the statement that the voluntary hospital with a medical school works at a higher professional standard and at a higher *pre-sure* than a Poor Law hospital. Is it not high time that the Ministry of Health insisted on the publication of a proper medical report on the work of Poor Law hospitals, in place of the absurd travesty of an annual report at present issued to and by the guardians? It is not medical and therefore valueless, such an innovation would, I think, prove that Mr Herbert Eason's deductions are erroneous at least as regards this hospital.

3. The relations between outside medical practitioners and the members of the staff of this hospital are of the most cordial nature, largely owing to the attempts at out-patient and follow-up treatment made by the latter, entirely on their own initiative and largely at their own personal expense. No fears need exist as to the danger of antagonism from general practitioners to a further improvement in the hospital service. They have free access to the patients whom they send us and are welcomed, but very few have the time to take advantage of this.

4. The question of the control of the proposed unified system is of primary importance. I should like to suggest that Mr Herbert Eason's simile of the elephant and the eggs should be reversed, making the voluntary hospitals take the place of the elephant. Given that point No. 1 is true, this must be so, is it wise? Medical men are but human, and has it been proved that the voluntary system is exclusively for the benefit of the patient? This is the point at issue. The provision of an efficient and well paid professional staff is quite another matter. At present many patients get preferential admission to voluntary hospitals by being able to pay a consulting fee beforehand, and the livelihood of the member of the voluntary staff depends on his impressing the student, the future general practitioner, with his medical wisdom and power. Hence one of the difficulties in arranging for students to use the immense field of clinical material in Poor Law hospitals. No blame is to be attached for this, but is it perfect, and should it be perpetuated by giving the voluntary hospitals control of the unified service? I should suggest that the staffs of the Poor Law hospitals who are qualified academically and in experience should have equal voice.

Finally, have the voluntary hospitals reached such an acme of perfection as to make them the ideal? Experience of Belgian, German, and Austrian hospitals, and a credible report of American hospitals, make me answer in the negative. Surely this is the time to take a very wide view and, holding neither to the rather sentimental voluntary system nor to the matter-of-fact Poor Law system, to incorporate the good points of all systems in a new hospital service. The medical profession as a whole is ready for it, and the public would welcome it.

May I add that I hold no brief for the full-time Poor Law medical service—very strongly the reverse?—I am, etc.,

J. S. M. CONNELL, F.P.C.S.D.,  
Gynaecological and Obstetric Officer

Dudley Road Hospital Birmingham Oct. 2nd

### POOR LAW MEDICAL SERVICE

SIR,—My review of Poor Law as a medical career (September 17th, p. 519) seems to have opened up the vexed question of Poor Law medical administration in general. Dr MacWilliam (October 1st, p. 614) appears to voice some of the sentiments of the editor of the *Poor Law Officers' Journal* and of someone who writes regularly in that paper over the pseudonym of 'Medico.' Dr MacWilliam's statement that there are instances of cordial relations in large mixed institutions is probably true, but the converse is also unfortunately true. Further, he does not state whether his own appointment is full-time and resident, also, Liverpool has its separate infirmary which makes a considerable difference. He also remarks that friction is not invariably the fault of the lay staff. I will go further and say that it is not the fault of either side, but of a system which in a certain type of institution makes a nice atmosphere difficult or impossible.

Dr Sunderland (October 1st, p. 614) comes much nearer the root of the matter when he states that of over 600 unions in England and Wales only about fifty have separate infirmaries. These figures should speak for themselves. He also refers to the lack of liaison between Poor Law doctors. This point is of vast importance in the interests of professional organization.

The interests of doctors in Poor Law are not sufficiently centralized in the British Medical Association. Some of them belong to the Poor Law Medical Officers' Association, some to a medical superintendents' association, some to the Poor Law Officers' Association, some to more than one of these and some probably to none. I belonged to the Poor Law Officers' Association until I realized that in the event of a clash between medical and lay interests in Poor Law there is only one sound defence—our own Association. The Poor Law Officers' Association could not be expected by the very nature of its membership to guard our interests as our own Association could and would do. I had convincing proof of this over my own appointment. I consider that the British Medical Association should have all available information from any smaller medical association in Poor Law, and so be at all times fully informed. There

is good reason to suppose that such information will be extremely useful

In order to clarify the position in institutions as I see it, they may be conveniently grouped under three heads

1 *Large Unions*, having a separate infirmary with a medical superintendent, and a general institution with a master and matron. This is the obvious and ideal plan

2 *Small Unions*, having one general institution for all purposes, with a master and matron, no training school for nurses, no resident doctor. This system works very well, and relations between master, matron, and part time doctor are easily maintained on a cordial footing

3 *Intermediate Unions*, large enough to employ a full-time resident doctor, having a training school for nurses and frequently a consulting staff, and doing a fair amount of acute work. The number of these "mixed" institutions can be imagined from Dr Sunderland's figures, and they are the type of institution to which my original letter applied adverse criticism. My view is that, once an institution reaches the stage outlined above and becomes a recognized training school for nurses, its administration should be changed. The best remedy is the building of an entirely separate infirmary if the town can afford it, leaving the master and matron in charge of the general institution. So acute has this problem become that attempts have been made to separate the two administrations while still more or less under the same roof. This is not generally regarded as highly successful, and it is expensive for the results obtained. Failing the building of a new infirmary, I take the view that the next best thing is the appointment of a medical superintendent with the nominal title of master as well. I believe I am one of about three medical men with personal experience of this, and I believe that the result has been a smooth administration in each case. This system has now been in operation in Reading for some six or seven years. So satisfactory has it been to all concerned that when my predecessor retired some fifteen months ago there was not the smallest chance of reversion to the old type of administration.

I have been at pains to amplify my previous remarks for two reasons. First, as far as the British Medical Association is concerned, I believe that more exhaustive information on Poor Law is imperative. Secondly, my original letter has been construed in one quarter as a general onslaught on the workhouse master. Such an attack by me on another class of officer in the same service would be unfair, not to mention the waste of time. At the same time, I can appreciate the fact that my views on one class of institution would in effect deprive workhouse masters of many of the best appointments open to them. I have reached my conclusions fairly and without prejudice, from my own experiences and those of others, and I am certain that they are at least worthy of note by any prospective entrant to the service.—I am, etc.,

Battle Infirmary, Reading, Oct 1st

D CARIL THOMAS

SIR,—In view of Dr MacWilliam's letter of October 1st (p. 614) I beg further space to point out that the main regulations governing Poor Law institutions which are not separate infirmaries are contained in the Poor Law Institutions Order, 1913, issued by the Local Government Board. This order modified but maintained the general effect of the "Consolidated Orders" dating from about 1840. Any sort of division or the institution into departments is discountenanced and entire management is placed in one pair of hands. This was a workable arrangement universally eighty years ago and is still workable in undeveloped institutions, but in all others, and especially where a whole-time medical staff is employed, observance of the present regulations in detail would cause such difficulty that by tacit consent it has been evaded everywhere.

It follows that there are variations of actual procedure under the same order, and that medical officers will form varying opinions of Poor Law work. Hospitals have gone ahead most where the order was most ignored. Why should the Poor Law retain a scheme of administration which would ruin a growing hospital when observed fully, and which seriously hinders growth when it is partially observed? It would be easy to make a readjustment without costing the ratepayers a penny. The Ministry of

Health mooted this in 1922, but apparently dropped the idea later.

The real question at issue goes far beyond any alleged antipathy between masters and doctors—I am, etc.,

Southend-on-Sea, Oct 2nd

R A S SUNDERLAND

## SURGERY OF THE TONGUE

SIR,—Mr Duncan Fitzwilliams, in his textbook *The Tongue and its Diseases*, reviewed in your issue of October 1st at page 596, refers to the Butlin series of cases. In my opinion Butlin reached the acme of success, now more than a quarter of a century ago. Happily, owing to advances in the application of radium, and more especially the exact regulation of the dosage, there are no longer required surgical procedures involving various degrees of deformity, defective articulation, and difficulties in swallowing saliva and in masticating food—squamous-celled carcinoma disappears under radium without leaving such deformities. As one instance among others of the benefit reached by surgery under Butlin, I saw the other day a patient in good health twenty years after Butlin had removed half the tongue and the pillar of the fauces. Subsequently, whilst, owing to illness, Butlin had only to stand by one side of the neck was dissected down to the clavicle, including the removal of the sternomastoid and anterior border of the trapezius. There persists a defect in articulation and in the elevation of the arm above the shoulder.

On the other hand, the treatment of the infection of the neck has not yet been solved. The question includes not only the glands found microscopically to be already invaded by the squamous-celled carcinoma, but also those exhibiting a small cell infiltration, whether on one side of the neck or on both.—I am, etc.,

London Oct 1st

WALTER G SPENCER

## PIRYXIA DURING THE PUERPERIUM

SIR,—My experiences of the practical working of the new Order (1926), whereby a woman who within twenty-one days of childbirth or miscarriage develops a temperature of 100.4° F and maintains it during a period of twenty-four hours must be notified to the public health authority, may be of interest to some readers.

On August 17th last I attended a confinement, and a went well until August 23rd, when the woman got a slight rigor in the early morning. At 10 a.m. her temperature was 100°, at 10 p.m. 100°, but on August 24th at 2 p.m. it was 102°. Thus ptyxia went on till August 31st, with an average of 99° in the mornings and 101.8° at night. The only other symptom the whole time was slight headache, there were no abdominal symptoms whatsoever. All appearances the lochia were normal. The patient never felt ill, she took her food well and slept well, and her bowels were normal. On August 24th I notified the case as one of "puerperal ptyxia." I practise single-handed in a county village, and we have a trained nurse who is also trained and certificated midwife. This nurse was in charge of the case. She was at once suspended from attending midwifery cases by the county medical officer, who informed her by letter that as she was attending a case of "puerperal fever" she must not resume duty till given permission by the local medical officer of health. On September 21st, exactly one month afterwards, she was allowed to resume duty.

On August 26th, or three days after onset of ptyxia in the first case, I had to attend another confinement, and I had to send six miles to get a neighbouring village nurse. I did not attend the case myself, my friend the district medical officer of health visited it for me, and on the second day the woman had a temperature of 100° at 9 a.m. and 101.6° at night, but for the next four days it did not rise above 100.4°, except on one occasion, when it was 101.4° at 8 p.m. This woman had a good deal of abdominal pain and distension, which continued for four days till the bowels well opened, when the whole condition cleared.

up, and, rightly or wrongly, I regarded the bowel condition as the sole cause of the puerperia because the lochia were normal and the improvement began immediately after the evacuation of the foul bowel contents. Here again the district nursing inspector suspended a special men nurse who had to get to liberate the one who had to send six miles for

On September 3rd I attended personally a third confinement—they were all in the village—and another new nurse had to be got for the patient. Fortunately this case went on all right, but we had all this time two special nurses in addition to our own in this small country village and all for what? I have lived and worked here for over thirty five years, and we have carried on very well in all circumstances with one nurse and nothing has ever happened. I have never had in my life to certify a death from puerperal sepsis. Three nurses here all at once made a town's talk, and everybody wanted to know what had happened. We have a hard struggle to make up the yearly salary of one nurse, and how our nursing association is to meet the expense of all those other nurses I do not know.

It is interesting to note that our own nurse was suspended because she was in attendance upon a case of puerperal fever, whereas I notified it as puerperal puerperia. Are they synonymous terms, or what is really puerperal puerperia? My own opinion is that neither of these cases was puerperal fever in any sense of the term, and that all this notification and suspension of nurses is of no use or benefit to anybody. It causes a lot of anxiety, public gossip, and vexation, and we have a right to know where we stand. These nurses apparently take the mouth temperature of living women from the time of delivery right and morning, so no wonder if puerperal puerperia gets on the increase. Is the nurse to be suspended in every case of puerperal puerperia irrespective of the cause? It would seem that it is so.

Surely a living woman may run a little temperature during the early days of her confinement without its being due to puerperal sepsis. I venture to think the majority of medical men doing midwifery work think this meddling legislation has gone a bit too far. No wonder men are giving up the work. After my recent experience I do not blame them—I am, etc.,

FELTON Northumberland Sept. 28rd.

POET A WELSH

#### SECOND ATTACK OF PITIRIASIS ROSEA

SIR,—I am deeply interested in the memorandum on 'Pitiriasis rosea—a second attack,' contributed by Dr Gordon Edleston to your issue of September 24th (p. 549).

I have been on the look out for second attacks of this disease in the same patient ever since the publication of my paper upon pitiriasis rosea in 1914 (not 1915). In the discussion which followed my paper (*British Journal of Dermatology* 1914, p. 135 et seq.) Whitfield mentioned one experience of a second attack, Doro mentioned a doubtful instance and Gray—who was not, unfortunately reported—said that he had seen a case of pitiriasis rosea in a patient who several years previously had been under the care of Dr Radcliffe Crocker, who had diagnosed pitiriasis rosea at that time.

I am still firmly of opinion that recurrences are extremely rare, and I have not myself met with a single instance of a well authenticated repetition of the disease in the same patient since the case reported by me in 1914. The implication of infection conveyed by Dr Edleston's experience is, I think, equally uncommon. I am, etc.,

LONDON W. Oct. 3rd.

C. GRAHAM LITTLE

#### THE ASSOCIATION ANNUAL MEETINGS

SIR,—As a member of the British Medical Association of over twenty years standing I plead for a re-arranging of our sectional programme. There is too much overlapping of our more important sections. Everybody who wishes to do so should be able to attend the whole of such generally attractive branches as Medicine, Surgery, Obstetrics and Gynaecology and Children's Diseases. Overlapping there must be and Tropical Medicine and the new and promising

Historical Section may be taken as examples of secondary interest.

A large number of us attend yearly wishing to make the most of our time, but, too often, at the end of the week, we find important sections have had to be left once more unvisited. We devote a week of our time, and far more than a week of our incomes, to sit down to what is in all respects a most generous repast and—wonder how only partially satisfied, with many wholesome and much desired dishes on the menu perforce untasted. Is there any insurmountable objection to the eight most extensively attended sections being so listed that four may be taken on the four working mornings at 10 a.m. and the other four at 2.30 or preferably at 2.15 p.m.? I dare wager "a cock to Esculapius" that the two largest available halls would be comfortably filled by adopting this course, and that speakers and auditors would gain by it.

Equally important to many of us would be a modification of the present material of the sections themselves. Year by year they tend to become—each of them, I make no distinction—more and more arenas in which carefully selected and distinguished specialists present, rather to each other than to us, carefully prepared and highly advanced views on the subject laid down. We mutely watch the succession of learned enthusiasts quickly following each other with one eye on their proof sheets and the other on the clock. Over and over again my fellow members have said to me on these occasions, "What cannot a larger number of these most valuable and very technical papers be kept for the appropriate learned societies and their journals whilst we have back again the old style broad based representations and discussions of the matter in hand?"

Some of us feel that the sections are becoming too advanced. We feel there is a distinct danger of the meetings becoming the parade ground of the professors of the universities and medical schools. Direct the big 16-inch guns on the target if you like—we love to see the practice they make and rejoice in their excellence. But—give the rest of the artillery a chance to get in a few shots or it will lose some of its polish and tend to be kept away back in the arsenal—I am, etc.,

MOSCOW S.F. 6th

C. MITCHELL

#### DRIED COMPLEMENT IN THE TROPICS

SIR,—I was interested to read of Dr. Neave Kingsbury's experience with dried complement (September 17th, p. 518), as on the one occasion when I tried this material my results were no more favourable.

Having had some trouble with my guinea pigs two or three years ago in India I tried a sample of dried complement—also of German manufacture—which had recently been sent to the institute where I was working.

As in Dr. Kingsbury's case the material was put up in sealed capsules each of 0.1 gram and the directions stated that a 1/10 solution was equivalent to fresh guinea pig serum. A clear solution was obtained in this dilution, though only after a considerable time.

The test used was Method No. IV Medical Research Council (Special Report Series No. 14) in which a dilution of 1/30 of fresh serum is the lowest dilution considered suitable for use in the test proper—that is, 1/30 used without the addition of antigen in the preliminary complement titration test.

At this distance of time I fear I cannot remember the details of my results with the dried serum except that complete haemolysis was not obtained in half an hour with dilutions higher than 1/10 of the original solution of dried serum. Thereupon I concluded that either the sample was not a representative one or that the material, as prepared, was not suitable for the tropics.

Everyone I suppose knows how tricky guinea-pigs are in the matter of obtaining a satisfactory complement from them, but provided they can be got to breed, a great deal can be done by careful adjustment of their food and housing conditions, and it has been my experience that since we went into these points we have had no further difficulty with complement.

At the same time, there must be occasions when one's

guinea-pigs fail one, in spite of all efforts, and for such occasions a good sample of dried complement would be invaluable—I am, etc,

Cambridge Sept 17th

L. A. P. ANDERSON,  
Major, I.M.S.

#### FELO-DE-SE

SIR,—I would thank your correspondent "Medico-Legal" for his interesting reply (October 1st, p. 614) to my previous letter (September 17th, p. 518). The brevity of my letter appears to have left "Medico-Legal" insufficiently informed. For obvious reasons I did not ask you to publish the evidence which I gave to the coroner, though I did submit it to you for your own information; this possibly explains the fact that the reply in your footnote was more emphatic than that of "Medico-Legal". There was no *post-mortem* examination. My evidence included the statement "The operation performed proved that the deceased was not pregnant and that she had not recently been so." This statement was accepted by the coroner without question. There was no evidence of importance other than mine. The proved or accepted facts were that, though the woman believed herself to be pregnant, she was not in fact so, that it was her intention to procure abortion, and that no other person was concerned in the act which caused her death. I voted with satisfaction that "Medico-Legal" confirms my own opinion that, even had the verdict *felo-de-se* been according to law, such a verdict should not have been returned except after an inquest before a jury. It is, of course, not for me to appeal to the Lord Chancellor for a fresh inquest, and I doubt if the relatives will consider such a course expedient—I am, etc,

Manchester Oct 2nd

SIDNEY A. WINSTANLEY

#### "ETHER CLONUS" ALDEHYDE AND PEROXIDE

SIR,—In a letter under the above heading in your issue of September 24th (p. 566) Mr. H. Edmund G. Boyle draws attention to the dangers arising from the production of aldehyde and peroxide when oxygen or a mixture of  $O+N_2O$  is passed through ether during its administration for anaesthesia.

The production of peroxide under these conditions is well known to chemists, and it is important that it should be also understood by anaesthetists. There is a further point which is at least equally important—namely, that the rate of formation of peroxide increases greatly as the amount present increases, consequently an ether which contains initially even minute amounts of aldehyde or peroxide will be much more prone to this change than one which is free from it. I draw attention to this matter to emphasize the fact that an amount of peroxide which is undetectable by the *B.P.* test, to which Mr. Boyle refers, will still suffice to accelerate this change. Consequently much more delicate methods of detecting must be applied if the purity of ether is to be maintained at the standard needed for perfect anaesthesia. Details of a delicate method of testing, based on the use of ferrous thiocyanate, were worked out in these laboratories and published in the *Year Book of Pharmacy* (1924, p. 615).

The late Mr. S. R. Wilson of Manchester, in a paper on "Ether convulsions," published in the *Lancet* of May 28th, concluded that "the convulsions are toxic in origin and due to the presence of impurities in ether," and he also advocated the precautionary measure of using only pure ether.

In my view Mr. Boyle is right in drawing attention to the significance of minute amounts of impurities, but in defining pure ether we have to look to a much higher standard of purity than that secured by adopting the *B.P.* test used by Dr. W. Inglis Clarke as mentioned in Mr. Boyle's letter—I am, etc,

London, N., Sept 27th

The British Drug Houses Ltd

#### COURTESY CALLS

SIR,—I was interested in Dr. Rawdon Smith's letter on the subject of courtesy calls (September 17th, p. 520). Some years ago I joined an old established practitioner as

partner, and paid the usual calls on neighbouring practitioners. Not one of them returned my visit, and one gave me a very gloomy impression of the prospect of success in the district, and even recommended me to give up the idea of practising in the neighbourhood! I may have had an unfortunate experience, but if newly settled practitioners are accorded the same aloofness I was I am not surprised that courtesy calls are unpopular duties and often shirked—I am, etc,

September 18th

M.B., D.P.H.

#### Obituary

WILLEM EINTHOVEN, M.D., Ph.D.,

Professor of Physiology in the University of Leiden

THE death of Willem Einthoven, announced on September 29th, robs mankind of one of its most distinguished physiologists. Trained at Utrecht, he was appointed at the early age of 25 to the chair of physiology at Leiden; this post he held till this his 67th year. Unusually well trained and able in physics, Einthoven directed himself mainly to the development and perfection of recording instruments. Amongst these the most renowned is his famous string galvanometer. Starting his researches on the basis of the d'Arsionval galvanometer, he moved to the principle of Adair's instrument for recording submarine signals, an instrument which consisted of a very long single wire suspended vertically between the poles of a magnet. By greatly increasing the strength of the magnetic field by introducing relatively short and very thin, and therefore light, fibres, and by using an optical projection system of high magnification, he eventually constructed a galvanometer greatly surpassing all previous instruments in sensitivity and quickness of movement. More than twenty years were given to the perfection of this instrument, and of the subsidiary apparatus such as recording cameras and time signals, and he thus created a piece of apparatus which of its kind was of unparalleled delicacy and accuracy. The records yielded by his instrument directly represented in curvilinear form the changes in the flow of current from instant to instant, requiring no analysis, as did curves previously won by means of the highly developed capillary electrometer. It was this feature of quick response, with the consequent direct representation of current flow, that rendered his instrument peculiarly applicable in clinical observation. Einthoven's model formed the basis of the well known commercial model now in use in the hospitals and laboratories of five continents, but the sensitivity of Einthoven's own models has continued until the present time to outstrip by far that of all similar instruments.

Einthoven did more than place his wonderful apparatus at the disposal of other workers. He pointed to many of the ways in which it might be employed. Amongst these he called attention particularly to its capacity to portray the electrical events happening in the human heart. Modern electro-cardiography, and the analysis of irregular heart action by galvanometric means, may rightly be said to have been inspired by, and in large part founded upon, two papers of his published in 1906 and 1908. His adoption of separate leads, pairing the three sets of adjacent angles of an approximately equilateral triangle, and his theoretical calculations of the line of the heart's electrical axis from the resultant curves, has proved fundamental to much later work.

The application of Einthoven's galvanometer to the study of the physiology and pathology of the heart has followed quickly upon his description of the method, its full application to the study of electrical phenomena in other organs of the body has been more delayed. He himself illustrated the value of the instrument in recording the electrical events in nerve and other structures. For example, he succeeded in displaying impulses passing at each beat of the heart from this organ through the vagus nerve to the brain.

As early as 1894 he and Gehuk described a method of registering heart sounds. Later he adapted the string galvanometer to the same purpose, a method that has been extensively and fruitfully followed up by others. In the

last years of his life he brought sound recording to a pitch of extraordinary perfection, using to this end a film so light that it responded directly to the sound waves agitating the atmosphere in which it lay, its movements being of sufficient amplitude to be recorded photographically. These were among the greatest of his achievements though they by no means exhaust them.

Einthoven's renown grew steadily and in recent years has found expression in many public honours conferred upon him, these culminated in the award of the Nobel prize for medicine in 1924 and in this country in his election last year to be a foreign member of the Royal Society.

Einthoven's work will be remembered for all time for the greatness of its contribution to method of observation. Einthoven himself will be remembered by those who knew him personally for his fascinating personality. A man of simple, almost of humble, habits he was untrusting in his work, in its exposition, and in the study of related problems. He awakened in both friends and associates a profound admiration by his genius, by the charming simplicity of his character, by his touching if not childlike modesty of thought and manner, by his patience, by his natural and profound courtesy, by the warmth of his hospitality to those privileged to enter his home by his unswerving devotion to truth in the most exacting sense. These noble qualities endeared him to all who knew him at all intimately.

THOMAS LEWIS

Einthoven was born in 1850 in Samarang (Java), where his father was a medical practitioner. After his father's death in 1870 his mother brought her six children home to Holland and settled in Utrecht, where he was educated. He became a student of medicine there in 1878, and after completing his course was assistant to Suelling, and to Donders in the physiological department. From that appointment he was called to the chair of physiology at Leyden, where he spent the remainder of his life.

We are indebted to Dr LEONARD HILL for the following brief reminiscence of a recent visit to Einthoven's laboratory.

It is just a year ago since I stood in Einthoven's laboratory in Leyden and was shown by him his last form of string galvanometer, in which the string was stretched in a vacuum and, so light and delicate was it, that the photographs of the string showed a ceaseless Brownian movement. Einthoven had there an instrument so responsive that he needed no valves to magnify the electrical effects which he wished to record and he discountenanced the use of such valves as likely to distort the true reaction. He was then engaged in recording the electrical variations of the sympathetic system of nerves in the living animal—variations set up by natural impulses passing down these nerves—a new and most interesting field of research. And this most charming and modest man of science is now dead, and the book of his records is closed and will receive no more entries from the hand of the master, but the work which Einthoven has done in introducing the string galvanometer as a means of diagnosis, in elucidating the action of the heart in health and disease, and in recording the natural impulses coursing down the nerves stands as a pattern of accuracy and will be carried on by his pupils, using those methods which he has perfected. Einthoven is one of that band of scientific men which has made the University of Leyden so famous. He spoke English perfectly and was a most cordial friend to his English visitors, a man full of humour and a broad humanity.

#### SVANTE ARRHENIUS

Director of the Physical Chemical Department of the Nobel Institute, Stockholm

PROFESSOR SVANTE ARRHENIUS who died on October 2nd at the age of 68 is acknowledged to have been one of the masters of modern physical chemistry. This high place was achieved with one vivid theoretical contribution—his theory of electrolytic dissociation. Poincaré, in his book on the Foundations of Science writes: "There are facts common to several sciences which seem to be the source of streams

diverging in all directions. They are like that knoll of St. Gothard whence spring waters fertilizing four valleys." Such are the facts upon which is built the theory of electrolytic dissociation. No hypothesis has proved more fertile to our understanding of the behaviour of solutions. It has revolutionized our principles and methods of study. It has dominated every field of scientific inquiry in which the methods of chemistry find employment. We can afford to smile at the recollection that when Arrhenius presented the elements of his theory in a thesis for a doctorate it found small favour with his professors.

Biology has been particularly enriched by the conception of electrolytes and their ionization. Consider only the case of the dissociation of water and its relation to the activity of acids and bases. The modern technique of biochemistry, physiology, bacteriology, and experimental biology is dominated by the conception of the hydrogen ion concentration which derives immediately from this hypothesis. Building upon the foundations such men as Sørensen, Michaelis, Lawrence Henderson, Mansfield Clark, Van Slyke and J. Loeb have raised that amazing edifice of precise measurement, exact control and quantitative definition of vital phenomena such as we find at its highest in the modern statement of the intricate electrolyte equilibria of the blood and tissues. The whole complex physico-chemical equilibrium which we call the living cell will submit to no quantitative definition in terms which do not involve the principle of electrolytic equilibria. To trace in detail however the echoes of this hypothesis in physiology is, in a measure, to elude the most precious contribution of Arrhenius to biology. Arrhenius was one of those who insisted upon the imperative necessity for measurement in the study of vital phenomena. Les propriétés des corps sont les propriétés des nombres, remarked De Chancourtois. Arrhenius vigorously challenged those who contended that the notion of biology is mathematics was a mischievous thing. With the help of formulae," he wrote, "which may be empiric or rational, scientific progress will be much more rapid than without them, and as the experimental material merely the empiric formulae will probably give place to rational ones. So will new laws of nature be detected." His argument and his evidence are presented in his book *Quantitative Laws in Biological Chemistry* (1915). The same faith is seen in his collaboration with Madsen in the latter's extensive study of the chemistry of the immunological reactions. Here, again, his concern was to condense into formulae the regularities which were disclosed in the elusive reactions of toxins and antibodies, agglutinins, precipitins and lysins. The volume in which he told the story of this endeavour was quickly translated into English and published in the familiar book *Immunochemistry*. Arrhenius, who was born in 1859 near Uppsala, wrote in Swedish.

While we acclaim the imagination which gave birth to the theory of electrolytic dissociation we acknowledge the faith which taught us that although the "mathematical mill" would only grind out those same facts, which we put into it, yet would it grind them exceeding small.

R. K. C.

DR CHARLES GEORGE MACVICKER of Street who died on August 30th at the age of 64 was a native of Londonderry, and received his medical education at Belfast and Edinburgh, he graduated M.B. Ch.B., B.A.O. in 1891. He commenced medical practice at Almondsbury near Bristol, then removed to Isleham in Cambridgeshire, and from 1899 onwards lived at Street where he was medical officer to the Street district of the Wells Union and to the Abbey Grange School for mentally deficient children. He was a member of the visiting staff of the Butleigh Hospital, to which, at the time of his death, he was senior medical officer. He was a member of the committee of the Somerset County Nursing Association from its foundation. He was an ardent Conservative in politics, and for over twenty-two years had been a churchwarden serving under five successive rectors. He was vice-chairman of the parochial church council, vice-president of the Church of England Men's Society, and of the Rangers Guild, and the moving spirit in many other church activities. He was a council school manager and a member of the committee of Cox's Charity,

president of the local choral society and of the Street football club, and vice-president of the county football association and of the Street cricket club. He served as a magistrate for some years, and was an enthusiastic member of the Somerset Archaeological Society.

Dr. JOHN HAMILTON, who died on August 9th, was born in 1857, in Hamilton, Scotland, and received his medical education at Glasgow. He obtained the diplomas L.F.P.S. Glasg. in 1878 and the L.R.C.P. Ed. in 1882. He carried on medical practice in Eldon Square, Newcastle-on-Tyne, from 1881 to 1899, when he came to London, and subsequently removed to Edinburgh. After returning from practice in 1921 he visited Australia, India, and South Africa. He was acting as surgeon in the S.S. *Goolia* when she brought home the survivors of the *Ticessa* from Mauritius in the summer of 1923. For the last three years of his life he resided at Newcastle-on-Tyne.

The death took place at Edinburgh on September 16th, at the age of 84, of Dr. C. G. MACKAY, who for many years practised at Locherion, Ross-shire. Dr. Mackay was born at Dornoch in 1843, graduated M.B., C.M. at Glasgow University in 1873, and had spent most of his life in practice at Locherion, where he acted as medical officer of health for the parish. He was a great enthusiast for the Gaelic language and literature, and in a very special measure enjoyed the confidence and affection of the Gaelic-speaking patients over a very wide area of the Western Highlands.

By the sudden death of Dr. WILLIAM NEWLANDS CLIFMEY on September 27th the profession has lost one of its most energetic members. Born in Bootle in 1869, and educated at Merchant Taylors' School and University College, Liverpool, he obtained the diplomas M.R.C.S. and L.R.C.P. in 1891. After holding the appointments of junior and senior house-surgeon at the Bootle Borough Hospital, he commenced general practice locally, in 1896 he was appointed to the honorary surgical staff of this hospital. From that time to the day before his death his heart and soul were devoted to the work of the hospital, which he saw grow from year to year in extent and usefulness. He was a pioneer in x-ray photography and spent much time in developing this branch of the hospital work. During the war he served also as honorary surgeon to the Breeze Hill Auxiliary Hospital, and acted as chief medical officer to the venereal clinic at the Bootle Hospital. For some years he was a member of the borough council, he was also a member of the West Derby board of guardians. He was appointed a justice of the peace in 1903 and sat on the Bench the day before his death. He was for many years an active member of the British Medical Association. The funeral was held at St. Luke's Church, Great Crosby, on September 30th, when a large assembly of patients and friends bore eloquent testimony to the esteem and regard in which he was held by all classes of the community. He is survived by two sons, the younger of whom is a member of the medical profession.

## Universities and Colleges

### UNIVERSITY OF OXFORD

The degree days for the academic year 1927-28 are as follows at 2.30 p.m. on each occasion—*Michaelmas Term* 1927 Thursday, October 20th, Saturday November 26th Saturday, December 17th *Hilary Term* 1928 Thursday, January 26th Saturday, February 18th Saturday, March 31st *Trinity Term* 1928 Thursday, May 3rd, Saturday, June 9th, Thursday, June 28th, Saturday, July 21st.

### VICTORIA UNIVERSITY OF MANCHESTER

The following candidates have been approved in the examinations indicated:

D.P.H.—Part I J. S. Smith Part II J. Cunningham Barbara M. Angell M. V. Macdonald and S. P. Wilson

### UNIVERSITY OF GLASGOW

The following candidates have been approved at the examination indicated:

FINAL M.B. CH.B.—F. Adams J. Agnew R. W. Agnew Frances W. Anderson W. V. Ballard H. Bankhead J. Baxter W. Bowler J. M. Brewster G. Bryden R. M. Buchanan J. S. G. Burnett J. H. Cadas J. M. Chow F. Craik Margaret G. Crockett Isabella M. Currie J. Darling H. M. Davis I. M. C. Dewar F. D. J. S. Drummond J. E. Dunn L. C. Durie C. A. Ferguson H. R. Ferguson J. Fleming A. W. Fraser J. B. Fulton G. H. Gibson R. D. Gilchrist J. M. Gilston H. P. Goldman I. S. Graham J. C. Gunn T. Hamilton D. Hannah A. Hart A. K. Hill W. Hodgkison J. A. Houston W. Hunter L. L. Hurwich P. Jacob R. Jameson T. Tizzard M. Tisdale J. H. B. Wieso W. H. Wilkie A. D. Williamson Elizabeth R. W. Wilsa J. W. Wilson W. G. Wilson Elizabeth N. Young

\* With distinction in Surgery. † With distinction in Medicine. ‡ With distinction in Midwifery.

## The Services.

### VOLUNTARY AID DETACHMENTS

SUBSTANTIAL progress continues to be made in the organization of Voluntary Aid Detachments as part of the voluntary reserve of the medical services by the Crown, under the scheme which was launched four years ago with the approval of the Army Council. 321 detachments have now received official recognition, and their members number 20,077. Of these, 3,180 have undertaken an obligation to serve at home or abroad in the event of a national emergency, while the others have agreed to do duty as they may be required within reach of their homes.

### DEATHS IN THE SERVICES

SURGEON REAR ADMIRAL GEORGE ALBERT DREAPER, C.B., R.N. (ret.) died at the Royal Naval Hospital, Haslar, on June 28th, aged 65. He was the son of R. H. Draper, of Finsborough House, Colchester, co. Kilkenny, and was educated at the Carnarvon Medical School, Dublin, he took the L.R.C.S.I. in 1883 and the L.K.Q.C.P. in 1884. Entering the navy as surgeon in 1884, he became first surgeon in 1904, deputy surgeon general in 1913, and surgeon rear-admiral in 1919, he retired in 1923. He served as staff surgeon of H.M.S. *Magicienne* during the South African war, and also in East Africa in the Jubaland expedition in 1900-1, when he received the appreciation of the Admiralty, and gained the South Africa medal and the General African medal with Jubaland clasp. In 1904 he served as fleet surgeon in H.M.S. *Porpoise* in the Somali campaign, including the capture of the Mullah's stronghold at M. on April 21st, 1904, was mentioned in dispatches, and received the East African medal, with a clasp. From 1908 to 1910 he was in charge of the surgical wards at Chatham naval hospital, in 1911 he filled the corresponding appointment at Plymouth, and from 1916 to 1919 was in command of the naval hospital at Hong Kong. Subsequently he served till his retirement in command of Chatham naval hospital. He received the C.B. in 1920. In 1910 he married Constance Amy, daughter of Mr. Henry de Blaquiere of Fiddler's Gort but leaves no children.

Lieut. Colonel William Reed Murphy, D.S.O., Bengal Medical Service (ret.) died in London on August 7th, aged 77. He was educated at Clongoweswood College, co. Kildare, at Trinity College, Dublin and at the Merth Hospital where he won many prizes. After taking the L.R.C.S.I. in 1871, and the L.K.Q.C.P.I. in 1877, he entered the I.M.S. as assistant surgeon in March 1872, passed into the service second out of a very large batch (40). As the first man, the late Lieut. Colonel Alexander Crombie, C.B., had already gone through the Netley course as a candidate for the Army Medical Department in 1871 he went straight out to India and Murphy headed the Netley list and gained the Herbert prize. He attained the rank of brigade surgeon lieutenant colonel in October, 1896 and retired in July 1899. His whole career was passed in military employment, and he had a very fine war record. In 1878 he served in the Indian contingent called to the Mediterranean by Lord Beaconsfield when war with Turkey seemed to be imminent, and served in Malta and Cyprus. The expected war however, was avoided. His first active service was in the second Afghan war of 1878-80 when he took part in the action at Sufudim in the occupation of Kandahar. The action of Ahmed Khel Arzu and Patkro Shamir was mentioned in dispatches in 1878, and received the Afghan medal with patches. He subsequently served in many frontier campaigns. The expedition of 1888 was mentioned in dispatches and received the frontier medal with clasp. The Lushai campaign of 1892 (clasp) the Chin Lushai campaign (1889-90) he was principal medical officer, was mentioned in dispatches and was awarded the D.S.O. and another clasp. He was in the Chitral campaign of 1891 and the relief force (medal with clasp), the Tirah campaign of 1897-98 with the Kurram Kohat force, and a principal medical officer of the Kurram movable column. He was retired in 1913 in dispatches. Nearly twenty years after his retirement he was granted a good service pension on July 6th 1913.

## Medical News.

SIR JOHN ROSE BRADFORD, president of the Royal College of Physicians will deliver an introductory address on 'The study of medicine' at the opening of the winter session of the Durham College of Medicine, Newcastle on Tyne, on October 11th.

SIR WILLIAM WILLCOX will deliver his presidential address at the meeting of the Medical Legal Society at the house of the Medical Society of London, 11, Chandos Street W 1 on Thursday, October 27th, at 8.30 p.m.

UNDER the auspices of the Child Study Society, London a course of lectures and discussions will be held at the Royal Sanitary Institute on Thursdays at 6 p.m. from October 13th to December 1st inclusive. The first lecture will be delivered by Dr E. A. Hamilton Pearson on the subject of the normal child. On January 4th a conference of educational associations will be held at University College when the chairman will be the Hon. Sir John A. Cockburn, K.C.M.G. M.D., president of the Child Study Society, and Dr David Forsyth will speak on the subject of 'These first five years.'

THE British Institute of Philosophical Studies will hold a meeting at the Royal Society of Arts on Tuesday next at 8.15 p.m. to hear lectures on the standpoints of Freud and Jung by Drs John Rickman and H. G. Baynes. Professor C. Spearman F.R.S. will take the chair. Tickets of admission can be obtained from Mr Sydney E. Hooper, Director of Studies at the offices of the Institute 88, Kingsway, W.C.2.

DR. J. S. OWENS will deliver a lecture on atmospheric pollution under the auspices of the Institution of Heating and Ventilating Engineers at the Cotton Hall, Westminster on October 11th, at 6.45 p.m.

A LECTURE in German on Jewish health problems in Eastern Europe will be delivered by Dr Julius Brintzlin, ex-Minister of the Lithuanian Government at the Jews' College, Grafton Street W.1 on October 9th at 4.30 p.m. The chair will be taken by Mr A. H. Levi F.R.C.S.

THE Birmingham and District Edinburgh University Club will hold its twenty-third annual dinner at the Queen's Hotel Birmingham on Thursday November 10th at 7.30 p.m. The chair will be taken by Dr E. A. Milner and Sir Robert Philip. President of the British Medical Association will be guest of the evening. Membership of the club is open to all male graduates of the university, and it is hoped that gentlemen who desire to be present, but who have not received notice of the dinner will communicate with the honorary secretary Dr Ernest Bulmer 87 Cornwall Street Birmingham before November 3rd.

THE London Branch of the Bristol University Association of Alumni will hold its sixth annual dinner on Friday, October 28th, at 7.45 p.m. at the Criterion Restaurant. The Chancellor of the University Viscount Haldane will preside and Professor Francis, Pro-Vice-Chancellor, will be guest of the evening. The dinner (tickets 9s.) will be followed by dancing in the ballroom (3s. 6d. extra). Applications should be made to the honorary secretary, Dr Elizabeth Casson 10, Victoria Sanatorium, Virginia Water.

THE Caledonian Medical Society will hold its annual meeting at University College Dundee under the presidency of Dr Angus MacGillivray, chief of the Dundee Highland Society on Friday, October 14th. The annual dinner will follow at 11.15 a.m. South Lindsay Street, Dundee. On the Saturday the members will pay a visit to St Andrews in the invitation of the University Court.

DURING the winter session a series of clinical meetings will be held at the Belgrave Hospital for Children 1 Clapham Road, S.W.9 on the second Wednesday of the month at 3.30 p.m., beginning on October 12th. The meetings will be conducted by members of the staff, and medical practitioners are invited to attend.

MR. V. S. MAYOT will give a special demonstration for the Fellowship of Medicine at the Central London Ophthalmic Hospital on October 11th at 4 p.m., free to medical practitioners. A clinical course in progress at the Central London Hospital Nose and Ear Hospital will continue for two further weeks. On four successive Wednesdays at 5.15 p.m., October 12th Dr Heald will give a series of lecture-demonstrations to enable medical practitioners to familiarize themselves with recent advances in medical electrical treatment. An all-day course in diseases of children will be held by the Paddington Green Children's Hospital and the Victoria Hospital for Children from October 17th to 29th and a two-week course in gynaecology will begin at the Chelsea Hospital for Women on October 17th. During October and November a compre-

hensive course will be held at the National Hospital, Queen Square consisting of general neurology, pathology of the nervous system, methods of examination and the anatomy and physiology of the nervous system. A series of demonstrations on the diagnosis and treatment of diseases of the eye will be given at the Royal Eye Hospital on Mondays to Fridays, at 3 p.m., beginning October 24th and continuing until November 5th. On October 17th Sir Humphry Rolleston will give the opening lecture of the series of lectures arranged by the Fellowship of Medicine on practical hints on medicine, surgery, and the allied specialties, at the Medical Society of London, 11, Chandos Street W.1, at 5 p.m. he will deal with the diagnosis and treatment of some endocrine disorders. Copies of syllabuses are obtainable from the Secretary of the Fellowship, 1, Wimpole Street W.1.

THE annual Corporate Communion of the Guild of St. Luke will be held at the Grosvenor Chapel, South Audley Street, W.1, on St. Luke's Day, October 18th at 8.15 a.m. It will be followed by breakfast at Lipton's Cafe 484, Oxford Street, if sufficient members signify their wish to attend. The annual general chapter will be held on the same day at King's College Strand at 5.30 p.m. The Bishop of Southwark will preach at the annual festival Evensong in Westminster Abbey on October 23rd, at 6.30 p.m. Further information may be obtained from Miss J. S. Moore King's College Strand W.C.2.

THE congress of French specialising physicians will be held in Paris under the presidency of Professor Fossier from October 11th to 15th when the following subjects will be discussed: (1) Symptomatology of septicaemia introduced by P. Gastinel and J. Reilly of Paris. (2) Pathology of oedema introduced by F. Aubert and P. Mauriac of Bordeaux. (3) Medical indication and therapeutic value ofolecotomy introduced by N. Fiesinger and P. L. Brodin of Paris.

THE following congresses will be held in Italy this month. The 11th congress of the Italian Association of Hygiene meets at Rome from October 12th to 16th when papers will be read on hygiene and labour, by Professor A. Sclavo of Sclavo the provision of milk by Professor F. Abba of Turin the prophylaxis of typhoid fever by Professor G. Leoni of Rome the disposal of rubbish by Professor P. Pulber and Engineer G. Rodella of Genoa the rural school and the anti-tubercular campaign in the Agro Romano by Dr G. Lescar of Rome. Further information can be obtained from the general secretary Dr Giovanni Palomba, via G. Belli 27 Rome. The twenty-third congress of the Italian Society of Laryngology, Rhinology and Otolaryngology will be held in Parma from October 22nd to 24th inclusive. Details can be obtained from Professor F. Lasagna, Clinica Otorinolaringologica. The second Italian Congress for Combating Tuberculosis to be held in Milan from October 23rd to 26th, will be under the presidency of Professor E. Belloni. The general secretary is Professor Andrea Scarpellini via Palermo 6, Milan. The seventh Italian Congress of Industrial Medicine will be held at Parma, Modena and Carrara under the presidency of Professor G. Gahbi, from October 24th to 26th inclusive when the following papers will be read: (1) Pathology of electricity and x-rays by Professors G. Arellio and E. Pignatelli (2) tuberculosis and emigration by Professor G. Allevi.

THE Chief Justice Storstad Eireann has appointed Dr Edward E. Lennon to be one of his Medical Visitors in Lunacy in succession to Sir William de Courcy Wheeler M.D. resigned.

DR. H. P. NEWSHOLME medical officer of health for Croydon has been recommended as medical officer of health for Birmingham in succession to Sir John Poberison, who is retiring after twenty-five years' service. Dr Newsholme received his medical education at Oxford and St. Thomas's Hospital and has held appointments as assistant medical officer of health at Brighton, Southend and on the Surrey and Wiltshire County Councils. Before going to Croydon he was medical officer of health for the North Riding of Yorkshire.

THE Board of Education has issued two further documents (price 2d. each) in its Physical Training Series one on this training in secondary schools and the other encouraging a more extended education than that provided in the syllabuses of the Board. It has also issued a supplement on physical training, for older girls (price 4d.) and a reference book for gymnastic training, for boys (price 3s. 6d.). These may all be obtained from H.M. Stationery Office or through any bookseller.

DR. KARL SICK professor of surgery at Hamburg University, has been nominated an honorary professor by the Turkish Government for his help in the organization of medical education in Turkey.

AT the International Dental Congress recently held at Copenhagen the executive committee awarded the Miller prize, founded in 1910 to Professor Wilhelm Dieck director of the Dental Institute of Berlin University.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Antiology Westcent, London*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London*

**MEDICAL SECRETARY**, *Mediscera Westcent, London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus, Dublin*, telephone 4737 Dublin) and of the Scottish Office, 6, Drumshengh Gardens, Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh).

### QUERIES AND ANSWERS

#### OXALURIA

"**INQUIRER**" writes: I have found oxaluria a growing trouble among my patients. Dieting gives undoubted results, but difficulty arises from the wholesale condemnation of "green and root vegetables." Years ago a French journal published an extensive list of the oxalic content of foods, unfortunately, I have lost the journal. Can any reader give a reference to information on this point?

#### EXPECTATION OF LIFE

"**M S**" wishes to know the average expectation of life of clergy men. How far down the list do they come?

\* \* We do not know of any recent analysis of the data but there is no reason to doubt that the clergy still retain their pride of place as the longest lived members of the community. According to Collis and Greenwood (*The Health of the Industrial Worker*, p. 74), who used the mortality figures of 1900-2, the expectation of life at age 20 of clergy (the census data—that is, including ministers of the Free Churches, Roman Catholic priests, etc.) was 47.1 years the greatest in their list, the next highest figure was 46.2 years for agricultural labourers. According to the mortality figures of 1910-12 (the most recent available) the rates of mortality of clergy and agricultural labourers are still the most favourable among the large groups, so that the expectations of life—which are based upon the rates of mortality—must also still be the best, perhaps a year or two better than the figures of twenty years ago.

#### A PRESCRIPTION FOR EPILEPSY

"**MEDICUS**" writes: I beg to call attention to what seems to me an excellent remedy for epilepsy. The treatment has been tried on a man, aged 42 who has suffered from petit mal for thirty-eight years, formerly having 200 attacks a year, but now only forty and improving. He had been treated by many distinguished physicians but with little or no benefit. Potassium bromide is generally regarded as the essential drug but the great difficulty in its use is the onset of bromism when the salt is given in sufficient amount to keep down the attacks. In the treatment here recommended bromide is still an essential, but combined with another drug that wards off the bromism. The patient has been under my observation for a year and is greatly improved in health. Below is given the prescription.

Pot bromid	3i
Borax	3ii
Mist pyrethri	3ii
Aquum	ad 3ii

Sig. Take one teaspoonful in a little water three times daily after food.

The "mist pyrethri" is made as follows:

Tinct pyrethri	1 an	mj
Formalin		
Tinct lavandulae	eo	ad 3ii

M ft mitte sup (ie 96 doses)

The general instructions given are: Attend to teeth and bowels, avoid red meat, which is toxic in epileptics, take ripe fruit, and plenty of vegetables and salads, attend also to mental hygiene.

### INCOME TAX

#### Liable, but not Assessed

"**J E K**" considers he has been liable to income tax from April, 1925, onwards but so far he has not received any official inquiry or request for a declaration of income. Ought he to take the initiative?

\* \* It seems that the posting on church doors of a notice to return income for assessment is sufficient to create a legal liability to render a return. "J E K's" safest course is to write to the local inspector of taxes saying that, as he may be liable to payment of income tax, he would like to receive one of the statutory forms of return for the current year. If, when the return is examined, the inspector requires particulars for previous years, they should be given, as an assessment for 1925-6 may be made at any time up to April 5th, 1932.

### LETTERS, NOTES, ETC

#### TREATMENT OF MALARIA

DR EDWIN A. NEAIBY (London, W) writes: While science in capable hands, such as those of the lamented Adrian Stokes is seeking to break the etiological chain which leads up to yellow fever and aims at the banishment of the disease from its remaining haunts in tropical America and West Africa, it would be of interest to know what treatment is commonly in use at present day. Steinberg's (mercurial) mixture and Noguch's polyvalent serum seem to be sheet anchors in the textbooks—the former, presumably, being intended to act as a parasite-killer while the latter is a direct antitoxin, introduced since the bacterial origin of the disease became known. In 1889 I was much impressed by reading an article in an American medical journal on the comparative success (in a Florida epidemic of yellow fever) of such remedies as arsenic, phosphorus and the dilute venom of certain snakes—all agents having, in substantial doses, haemolytic properties. I am credibly informed that these drugs in suitably dilute form, still maintain their reputation in the tropical and subtropical regions of the New World, where they have mostly been tested. I do not see them mentioned in modern English textbooks, or that any medicinal treatment is regarded as of much value. If this is the case, the fact that the remedies are obviously selected in accordance with the homeopathic rule of similars should not nowadays deter practitioners from using such well attested drugs, coupled, of course, with the usual nursing and hygienic measures. Such remedies should, of course, be administered in accordance with the well known toxic therapeutic indications at suitable stages for suitable features of this disease.

#### GLYCOSURIA WITHOUT SYMPTOMS

DRS A. D. MCCALLUM and FRED BRADLEY (Preston) write: Within the past six months we have been consulted by two patients, of middle age, whose attention had been drawn to the fact that their trousers legs and boots were bespattered with spots attributable to the use of a public urinal and consequent drying of urine on these parts of their clothing. In both cases no other symptom of ill health was complained of and in both cases the urine was found to be loaded with sugar. We have previously had such a complaint made.

#### HERPES AND VARICELLA

DR ERIC KENDRICK (Coventry) writes to record two cases of venereal chicken pox following shingles. In each case an elderly sister first developed intercostal herpes, the younger brother, chicken pox later. The interval between the rashes was three and fourteen days respectively.

DR E. H. SWIFT (Uckfield) reports a case of herpes and shingles occurring simultaneously in a woman, aged 52, now under treatment. A very severe herpetic eruption developed over the area of the fifth left intercostal nerve on September 22nd. The patient appeared to be more ill during the next few days than usually the case and on September 26th a dentate varicella eruption appeared all over her body.

DR J. RAGLAN THOMAS (Exeter) writes that many years ago, at Llanelli, and subsequently in Exeter, he often noticed an association of cases of these complaints. He reports a recent case of a woman, aged 80 who on September 25th, had severe shingles in the forehead and scalp, along the lines of distribution of the supra-orbital nerve. This was followed next day by an eruption of herpetic character, running into blabs in the forehead area. On October 1st she developed a typical chicken pox over the whole trunk, front and back. Dr Thomas's case of chicken pox has been prevalent in Exeter for some time but has not as yet been able to trace the infection in his present case.

### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical schools, and of vacant resident and other appointments at local hospitals will be found at pages 51, 52, 53, 56, and 57 of our advertisements columns and advertisements as to partnerships, associations, and locumtenencies at pages 54 and 55. A short summary of vacant posts notified in the advertisements columns appears in the Supplement at page 143.

## DISCUSSION ON THE PATHOLOGY AND TREATMENT OF PERNICIOUS ANAEMIA

### I—PERNICIOUS ANAEMIA A SYMPTOM COMPLEX RATHER THAN A DISEASE\*

BY

G. LOVELL GUILFORD CMG, MD, FRCP ED,  
Professor of Medicine and Clinical Medicine, University of  
Edinburgh

THE clinical picture of pernicious anaemia is sufficiently well established and definite, subject to almost infinite variation though it is. The variations depend on the acuteness and severity of the disease, the prominence of special symptoms according to the part of the body specially disturbed—the bone marrow, the heart, the kidneys, the gastro-intestinal tract, the nervous system (brain, spinal cord, or peripheral nerves) and sometimes even the skin—and to the presence or absence of complications which may mark the primary condition to a greater or less extent. The clue to the mazes of this labyrinth is the examination of the blood, and the diagnosis can never be made with certainty unless this is done. The principal criteria are a high colour index, the presence of megalo- and, in the great majority of cases, leucopenia. Megaloblasts, if they can be found, are helpful, and the platelets are diminished in number, and are individually larger than usual. There may or may not be poikilocytosis, polychromasia, punctate basophilia and other less important changes. The high colour index, the most important of all, is of course due to the fact that pernicious anaemia is a megaloblastic anaemia, that red corpuscle formation has to a greater or less extent ceased to be normoblastic, and that the megaloblasts, left over from embryonic life, have resumed their earlier functions and are pouring out larger red corpuscles into the circulation than the normal ones. The importance of a high colour index is perhaps best shown by remembering how difficult it is to make a diagnosis of pernicious anaemia in remission, when the index has dropped to normal or below it and if there is no properly authenticated history. Unusual anisocytosis, a little punctate basophilia and a leucopenia are all that one can expect and these justify only a conjectural diagnosis.

Probably we are all agreed that pernicious anaemia is essentially a toxæmia—a toxæmia which affects the blood and bone marrow more profoundly and more constantly than any other organ but which may and often does affect also practically every organ in the body in varying degrees. This toxæmia affects certain sets of people with greater frequency. Pernicious anaemia is much more common in people in later middle life when resistance is sapped by other degenerative processes, and the occurrence of familial and hereditary cases is much too frequent to be a mere coincidence. Possibly there is among the people in hereditary or congenital weakness of the bone marrow just as there is in others such a weakness of parts of the nervous system. I have justified myself that the etiological cases cannot be explained by similarity in conditions of life.

The real problem before us is—what is the toxin? We can postulate certain things about it but we do not know its nature. It is usually slow in action gradually accumulating till its maximum effect is produced. If the organism recovers it recovers sometimes very rapidly either because the poison is excreted or because a relative immunity is produced. Then the process begins again and may be repeated several times. The toxin is generally regarded as haemolytic but there is very little real evidence that it is so in the sense of actual dissolution of corpuscles. It is more probable that both circulating corpuscles and those in process of formation in the marrow are poisoned and therefore more easily destroyed by the ordinary phagocytic processes in the marrow, spleen, haemolymph glands, liver and else-

where. It is probable also that the toxin in some way specially interferes with the normoblastic function of the marrow and inhibits it. It is certain that it inhibits the normal development of the neutrophil series of leucocytes, it is quite common to see cases in which the white count has never exceeded 4,000 per c. mm. with a low proportion of polymorphs even though septic processes have occurred, and have been successfully overcome, and in which post mortem the marrow is full of myelocytes with hardly a polymorph to be seen. Possibly the same sort of thing occurs with the normoblasts, the first sign of improvement in the blood is often a slight drop in the colour index, because the bin has been lifted and more reds of normal size are coming into the circulation. In some way the toxin interferes with the formation of blood plates. They are few and large in the early stages, increase and become smaller as improvement takes place, and may be numerous in remission. The toxin produces sclerosis in the spinal cord and scattered necrotic areas in the liver. Other changes might be added, such as chronic inflammatory lesions in the kidney, punctate basophilia in the reds, which is undoubtedly a toxic evidence, and so on, but enough has been said to show that the toxin is capable of producing widespread changes not only in the marrow and blood, but in all the other organs which have to do with the destruction or elimination of poisons, or which can be influenced by them. Further these changes are of the same kind as those which are accustomed to associate with microbial poisons, with the single exception of the high colour index. All the other septic anaemias using the word septic in the widest possible sense show a low colour index.

Can we recall any known organism of causing the disease? The answer is I think, so far in the negative. There is certainly no organism to be found in the blood itself. Countless blood cultures have given negative results and I can certify that no known stain enables us to demonstrate organisms of any kind in the plasma or corpuscles. The first organism to be accused was the streptococcus mainly because it was found in the mouth, stomach, and faeces of cases of pernicious anaemia but partly also because of fancied success in treatment with serum and vaccines. I shall have more to say of this latter part later on, but as regards the former we know how ubiquitous streptococci are. For many years back I have records of faecal cultures in all sorts of conditions and I am convinced that streptococci are not more common or more numerous in pernicious anaemia than in many other conditions, and, according to the latest studies, they are not of the haemolytic type at all. They certainly are not constantly present. The same applies to throat and other cultures. If a haemolytic streptococcus were really the cause of pernicious anaemia we should expect and should find an entirely different series of blood changes. The same applies to the *Bacillus coli* who claims have also been mooted, with still greater force.

The most recent prisoner at the bar is the *Bacillus welchii*, a non-proteolytic spore-bearing anaerobe, which is a normal inhabitant of the intestine and which can cause gas gangrene or wounds when they become infected with it. Mouch Kuhn and Torrey led the way in the study of *B. welchii* in this connection. They demonstrated that the faeces of 33 cases of pernicious anaemia contained a high number of *B. welchii* (and also of *B. coli* and streptococci) than those of normal persons. Of the three organisms the only one really haemolytic was the *B. welchii*. The other two were of the normal intestinal type. None of the four strains of *B. welchii* strongly haemolytic though they all were very more potent in this respect than strains from normal persons. Therefore the author points out that the most virulent strain of *B. welchii* is to be regarded as an anaerobic toxin-producing anaemia. It may be rather because it either excretes a number of active in the colon or more probably in the small intestine into which they might wander, or to unusual permeability of the intestinal wall to their toxins. I frankly it is unlikely that excessive numbers of organisms in the colon could alone produce a disease like pernicious anaemia and the next step is to demonstrate that organisms of the type normally found in the colon are present in the small intestine in pernicious anaemia in

\*The opening paper of a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Edinburgh 1917.

usually large numbers. There is already a considerable body of literature which tends to show that this actually occurs. The methods used are various, from the passage of the diodenal tube to the establishment of an ileostomy, but apparently every worker found the flora quantitatively increased, and many describe the invasion of the small intestine by colonic types. These most frequently found in excess were streptococci and *B. coli*, in most cases the technique used was not suited to demonstrate *B. welchii*. It is known that artificial stenosis of the ileum in dogs causes the flora of the small intestine to become the same as that of the colon, and Williams has shown that the same thing happens in man as the result of acute intestinal obstruction, while the striking curative effect of *B. welchii* antitoxic serum in his cases shows how potent that organism must be when it makes its way into the small intestine in large numbers. Kahn and Torrey have carried the indictment of this organism several stages further. They injected monkeys intravenously with *B. welchii* toxin in small doses, and claim to produce all the blood changes which are considered to be typical of pernicious anemia. In work which is not yet published they damaged the mucous membrane of the stomach of monkeys, and fed them with cultures of *B. welchii*. They then found in the blood and tissues changes identical with those found in pernicious anaemia in the human being. All the workers on this subject assume that the cause of the upward spread of the colonic flora is the gastric achylia which is present in the disease.

This is very strong evidence if it is confirmed, and we may be certain that the last word on the subject has not yet been said. We have all felt sure for many years that the intestine was a probable source of some of the toxins causing pernicious anemia, even though the deposit of hemosiderin in the liver is no proof of blood destruction in the portal system itself, as it occurs when hemolysis takes place in the general circulation.

It has often been suggested that some spirochaete or protozoon might be responsible, but so far no definite evidence against either has been adduced. A considerable amount of work has been done in America with the view of showing that sufferers harbour intestinal parasites of various kinds (other than bothrioccephalus), and that extinction of these is followed by cure.

A great deal of work, much of it bewildering to the non-chemist, has been done in the endeavour to show that a deficiency of cholesterol in the blood is wholly or partly responsible for haemolysis, and it is pretty definitely known that cholesterol is diminished in the blood in pernicious anemia. Unsaturated fatty acids, strongly haemolytic, are always present in the blood even in normal people, but are presumably kept in check by the cholesterol or some other antihemolytic body. It is conjectured rather than actually proved that the amount of haemolytic lipids in the blood is increased in pernicious anaemia, but there is no agreement among authors as to how the antagonism between the haemolytic substances and cholesterol acts upon the corpuscles so as to produce haemolysis. In any case, while some such action may be the means of haemolysis, it is obvious that a low cholesterol value and a high fatty acid value cannot be a primary change, but must be secondary to some general metabolic disturbance caused in some as yet unknown way. The spleen has been regarded as an important factor in this connexion, and it is stated that after removal of the spleen the cholesterol value in the blood is increased, and the fatty acids are more completely saturated, that blood corpuscles taken from the splenic vein are less resistant than those in the general circulation, and that after splenectomy in dogs the corpuscles become more resistant not only to hypotonic saline, but to other haemolytic agents. It seems to me, however, that while this may have an important bearing in such conditions as reholmic jaundice, in which the corpuscles are less resistant than normal and in which it is known that splenectomy causes improvement, it is far-fetched to transfer the conclusions to pernicious anaemia, in which the corpuscles are more resistant than normal, not only to hypotonic salt solutions, but probably to other haemolytics as well.

We must next consider the part played by gastric achylia

in the production of the disease. Achylia is practically constant, for while I have found hydrochloric acid present in a few cases in the test meal, I have sometimes also found it present in gastric cancers, in which its absence is just as much the rule. Cases are known in which, after relief lasting for years, pernicious anemia has developed. It has been shown that among the relatives of patients achylia is relatively frequent, though it must be admitted that achylia has not been sought for with the same keenness in the relatives of patients suffering from other diseases. It is, of course, known that it is of frequent occurrence, not only among normal people, but in a host of debilitating conditions of the most various sorts. Obviously the evidence I believe that achylia is the primary factor will hail with delight the recent work which I have quoted on the transformation of the flora of the small intestine. But there are many difficulties which have to be met. It must be demonstrated that persons with achylia show this intestinal transformation before they develop pernicious anemia, otherwise the change in flora might be secondary to the disease, and not its cause. Some explanation must be found for the fact that the achylia secondary to various debilitating diseases do not develop pernicious anemia, and that is especially the case with gastric cancer. I have only seen two cases of pernicious anemia associated with gastric cancer—an infinitesimal fraction of my experience of the disease, and as certainly accidental as its occasional association with cancer of the breast, the larynx, and other organs. One can imagine no other condition so likely to lead to floral transformation as gastric cancer, and yet the anemia which it produces is always one of low colour index. One of the most striking facts about pernicious anaemia is that it does not develop out of an anaemia of low colour index, but, as far as I can judge, is primary in the sense that it is megaloblastic from the beginning.

We must remember that what we may call cryptogenic or idiopathic pernicious anaemia is not the only form in which the disease occurs, but that there are large groups of cases in which the cause is known, though we do not always know how the causal condition acts.

I may cite first bothrioccephalus anemia, with a blood picture and symptoms identical with those of pernicious anemia, and in which cure follows the removal of the worm. Only a few of the persons harbouring the worm develop the disease, and it is suggested, on the one hand, that it is only those who have a pre-existing hemolytic weakness who do so, on the other, that it is only when segments of the parasite are digested, possibly because the worm is dead or enfeebled, that the toxic agent is set free in the intestine and absorbed from it. The toxic agent in this case is believed to be cholesterol oleate, which is not only haemolytic, but probably inhibits the normal blast function, and so fulfils two of my main postulates.

In contradistinction to this are the observations on the pernicious anemia of horses. The disease is believed to be due to the infestation of the gastric mucous membrane of the horse by the larvae of certain flies. A toxin apparently protein and not lipid is produced, which is carried in the blood, and can cause the disease when the blood is injected into other horses. In one case a human being is believed to have been infected from a horse. Here we have two different toxins of quite diverse character apparently producing the same effect in the blood, bone marrow, and other organs.

It is definitely established that a certain proportion of cases of sprue are also cases of pernicious anemia. I think the larger part of the anemic sprues that I have seen have had a low colour index, but it is possible that they may have been in remission so far as the pernicious anaemia was concerned, or may not have developed it. I have given details elsewhere of a number of cases in which the blood and other evidences were typically those of pernicious anemia, with the same tendency to remission and relapse, and many others are known. The cause of sprue is definitely established, a yeast (*Monilia*) has been considered to be the causal agent, but there seems grave doubt whether it is not a secondary saprophyte. In this connexion another group of cases, of which I have seen four examples, is of interest. These were persons who had either never been out of this country, or at least had never been in

any country where spruce is endemic. They were all typical pernicious anaemias, as far as their blood and symptoms could guide one—one of the severe fatal type, the other three milder and more chronic but with the usual tendency to remission and relapse. They all had stools like those of spruce, two had sore tongue, two had not. The pancreatic insufficiency, so far as one could judge, had preceded the development of pernicious anaemia. Indeed, in one of the patients a man of 34 pancreatic defect was known to have existed since he was 3. The blood had never been examined until I saw him first, a few months ago. Are we to enlarge the definition of spruce to include these cases? If not, in what way does the pancreatic defect act? Does the interference with digestion allow of the formation of a protein or of a lipid poison, or does it encourage the growth of organisms?

Other groups of cases are those caused by seplulis and malaria, in both of which the marrow is probably primarily affected, and both of which can be cured by curing the original disease.

A different type is that associated with pregnancy. It is not very uncommon and in my experience is not usually fatal though it may be so. No organismal infection has been demonstrated, and there is a general tendency to regard it as due to some metabolic disturbance interfering with the marrow. The cases that recover seem to do so completely, but some have been known to develop pernicious anaemia again in a later pregnancy.

Another condition which can produce the blood picture of pernicious anaemia is over radiation. It may do so in normal persons but seems more likely to do it in leukaemic patients in whom the marrow is already disturbed. An actual aplastic anaemia may be produced. Here there is no evidence of haemolysis, so far as is known but rather of normoblastic exhaustion. A considerable proportion of primary aplastic anaemias show a high colour index. We know nothing of the cause of the condition, whether it is a toxin or a depressing marrow reaction, a congenital marrow defect or a combination of the two. There are other poisons such as benzol and trinitrotoluene, which may have a similar effect.

The sum of all this is that there are many conditions known and unknown which can produce a megaloblastic anaemia that we cannot hope to discover the cause of pernicious anaemia because there are many causes. In other words pernicious anaemia is a symptom complex rather than a disease. What we hope will happen will be that gradually the great group of cryptogenetic cases which includes by far the largest proportion, will be eaten in on by discovery. Some error in the intestinal canal is probably the starting point of most of the cases of this group, but it does not follow that the error is always the same error and it seems to me that underlying its operation is probably the power of resistance, congenital or acquired of the blood and bone marrow to its influence. This determines whether, in two persons with the error  $x$  one shall develop pernicious anaemia, the other a secondary anaemia or none at all.

#### TREATMENT

The treatment of pernicious anaemia is unsatisfactory, as we all know from the point of view of ultimate cure, but it is possible to do a great deal for these cases, and it is most important to approach treatment in a hopeful spirit and not to allow oneself the patient, or his friends to be daunted by the unfortunate name of the disease. Nearly 100 per cent recover, or should recover, from a first attack the great majority will from a second. It is in the later relapses that real difficulty arises, and that our therapeutic resources are tested. But even then no stone should be left unturned, for there are many cases on record of complete recovery, and many more of very long remissions. My own best case is that of a lady who from 48 to 50 was very ill required several transfusions removed and has remained well till her present age of 70.

Past sunlight, fresh air, cheerful surroundings, general tone measures are as important as in any other toxic condition. Diet requires to be regulated by the patient's alimentary condition, and has to vary between the severe

simplicity of peptonized milk in cases with much distress, and a practically full diet when the stomach is not disturbed. Minot and Murphy have recently suggested a diet with a high complete protein value in which the main ingredients are liver meat preferably bullock's heart, fruit, and so on. My experience of this diet is limited, several patients who have had the courage to persevere with it have done well—one case is still in remission after two years—but it must be confessed that none of the cases had gastro-intestinal disturbance at any time and they had all been able to take large doses of arsenic in the early stages so that they would probably have done well in any case. Other cases have not borne the diet well or have rebelled against it. It is very important to regulate the bowels and vents cases that can stand it are always the better for colon lavage. Hydrochloric acid is used as a routine measure for in medium doses it certainly helps appetite and improves digestion, but I find that the huge doses that Hirst would have us use are not well borne, can hardly ever be persisted with, and have no advantages to compensate for the discomfort they cause. Of course, in cases associated with severe gastric catarrh the acid is not tolerated at all and one has to fall back on ordinary sedative measures.

Arsenic remains our standby and there is no doubt in my mind that the best way of giving it is as the hydrochloric solution by the mouth gradually increasing the dose till the patient's limit of tolerance is ascertained and continuing with the largest dose that can be taken with complete freedom from arsenical symptoms until in favourable cases a colour index below unity is attained. It should then be stopped and iron given instead. Iron is only useful in this disease at this stage and should never be given earlier. The tolerance of arsenic is one of the most useful prognostic indications we have. Patients who can take 10 minims three daily will almost always do well those who cannot get up to 5 minims generally will not. We do not know with certainty how arsenic acts. It is a stimulant to normoblastic regeneration and must be useful in that way, but I think most of us feel that it has some further action either antiseptic or toxic or antibacterial. If a patient cannot take arsenic by the mouth after the stomach has settled down his chances of recovery by the use of arsenic given in any other way are small indeed. I have satisfied myself by repeated clinical observations that cases recover more quickly with arsenic by the mouth than if it is given intravenously or intramuscularly either in simple solution or as the organic arsenics, and I have. I think, given a fair trial to all the latter. Therefore I am apt now only to turn to the organic arsenics when arsenic by the mouth has definitely failed—very rarely do they then succeed.

Mercuriochrome has been tried. I have given it intravenously in five cases. In three it had no effect beyond giving the patients very sore mouths in one it did not prevent a speedy fatal issue in the fifth it was brilliantly successful. It was a puerperal case the patient was very ill, could not take arsenic and was running a high swinging temperature without any discoverable cause. A single injection of mercuriochrome brought the fever to an end, and the patient began at once to improve under the usual treatment. Probably she was suffering from a septicæmia in addition to the pernicious anaemia, although the blood culture was negative.

Transfusion of blood was discussed in this Section last year at Nottingham and I need therefore only quote my conclusion then that it is not curative is sometimes not even useful but may be of great service in helping the patient round a critical corner when his vitality is exhausted by toxæmia, and may give him a chance to recover himself.

Curiously enough, normal horse serum given either intramuscularly or by the mouth sometimes seems to be of service when arsenic fails. I was led to try it originally by reported successes with anti-treptococcus serum. I could not persuade myself that the anti-treptococcal part of the serum could be of value and the occasional good result from the unfiltered serum justified that feeling. I understand that many cases are still treated with vaccines usually streptococcal, made from the patient's faeces or

stock. I tried these at one time, as I have tried almost everything that has been suggested as treatment for this disease, but satisfied myself that they were of no value. They are very apt also to cause severe reactions, even with the greatest care in dosage, which always throw the patient back. I have already given reasons for believing that streptococci play no part in causing the disease.

Intestinal antiseptics are not curative, but are often useful as adjuncts.

Splenectomy has come into vogue of late years, especially in America. It is a purely empirical procedure, for we really know nothing of the part which the spleen plays in the disease, and it can be done with fair safety, for it is extraordinary how well cases of pernicious anaemia will stand operation. But I have never been able to satisfy myself from published reports that the cases did any better than those treated in the ordinary way, or, generally speaking, so well, and I have never advised this operation. One observer has noted that if a relapse occurs after splenectomy it is usually the last.

Many other drugs and substances have been used which I forbear to mention. In no disease is it more difficult to estimate the effect of treatment, unless one has dealt with large series of cases, because of the tendency to remission which may come on at any moment without warning, and without cause. A recent case impressed this on me afresh.

A lady of over 70 was admitted to a nursing home delirious, febrile, sick and thoroughly poisoned looking with red cells numbering 760,000, and haemoglobin 20 per cent. She was so ill and feeble that even transfusion was not thought to be worth while, and she was treated simply by careful feeding and nursing and a little arsenic by the mouth. Within three days, far too soon for the arsenic to have acted, she had greatly improved, the haemoglobin had risen to 33 per cent., and within a month she was practically well with haemoglobin 76 per cent.

Had anything energetic been done—transfusion, splenectomy, massive doses of a serum or vaccine—she would have been hailed as a brilliant success for that particular line of treatment. The real truth is that if a case has made up its mind to have a remission it will have it, and no treatment, not even wrong treatment, will prevent it. These dramatic recoveries are more common in first and second attacks, but may occur even with later ones. One is inclined, therefore, to be sceptical about the result of any new line of treatment unless a large number of cases have been dealt with, and it has been found to be as useful in late attacks as in early ones.

Theoretically we ought to keep our cases under observation during remission, but we all know how difficult it is to do this. It is the time, however, in which anything that will build up the patient's resistance should be undertaken, and when we get a real explanation of the cause of the erythropoietic group, we may hope that remission will be the time when the cause or causes may be dealt with. So much attention is now being focused on the disease that we may surely hope for advance, though it will be made more probable by the chemist or the bacteriologist than by the clinician.

## II—HAEMOLYSIS AND THE BONE MARROW IN PERNICIOUS ANAEMIA

BY

W. K. HUNTER, M.D., D.Sc.,

Munich Professor of Medicine, University of Glasgow

PROFESSOR GULLAND's statement that the clinical picture of pernicious anaemia is well established and definite is true, but there is this difficulty—that the term, as used by different writers, has not always the same significance. For instance it is not that the proportion of recoveries in pernicious anaemia is at least 10 and possibly 20 per cent. again, that it is only one half per cent., and yet again that if a patient recovers the disease was not pernicious anaemia. These different writers have apparently a different conception as to what exactly constitutes pernicious anaemia. In considering the pathogenesis of the disease, however, we are mainly concerned with the interpretation of the symptoms and *post-mortem* appearances, and these, I think, are not in dispute.

Now the two most notable features in pernicious anaemia, from the point of view of its morbid anatomy and also of its symptomatology, are (1) the evidence in the liver and other tissues of increased destruction of red corpuscles, and (2) the marked changes, both macroscopic and microscopic, which are found in the bone marrow. It is on the latter points that the discussion as to the pathology of pernicious anaemia must centre. The two are doubtless related, but what the relation may be is not certainly determined. It has been held that the haemolysis is the primary event, and that the marrow change is due to an endeavour on the part of the blood-forming organs to compensate for the cells lost. A second view is that the marrow change is the primary one, and that the haemolysis is due to abnormal blood cells from an abnormal marrow undergoing destruction more rapidly than normal. The third view suggests that the haemolytic changes and the changes in the marrow are more or less coincident. All these theories presuppose the presence of a toxic substance acting on blood or marrow, or on both blood and marrow. In the pernicious anaemia due to the bothrioccephalus we know the source, and perhaps the nature, of the toxin, and we are aware that appearances like those of pernicious anaemia can be produced experimentally by certain haemolytic serums and by several chemical poisons. But the nature and source of the toxin in the vast majority of cases of pernicious anaemia are unknown. Many theories have been advanced. Predisposition without doubt must count for something. Professor Gulland has mentioned the occurrence of the disease in two or more members of the same family. There is the absence of free hydrochloric acid, which not only determines loss of an antiseptic to the stomach, but is often associated with the less vigorous and milder type of individual. Pernicious anaemia is a disease of late years, and I would emphasize the comparative frequency with which it is met in advanced life. I have noted, too, how often in cases of pernicious anaemia, in women at least, there is a history of "bloodlessness" during adolescence. As showing the tendency to "disturbance" of the marrow in the same family, I would quote the case of a woman with polycythemia rubra vera who inquired whether she had pernicious anaemia, as her brother had died of that disease three months previously.

As regards the exciting cause in pernicious anaemia, I always think of this disease as a subinfection of some sort, somewhat analogous to what is found in the marrow and biliary tracts, and possibly in diseases so different as Hodgkin's disease and disseminated sclerosis. All the conditions have periods of improvement and exacerbation, and in all of them the disease is most difficult to eradicate. The fever which is so frequent in the more acute phase of pernicious anaemia suggests an infective process, and when a patient with pernicious anaemia has fever the condition has usually become more or less critical, for the anaemia is then often rapidly progressive. In one typical case of pernicious anaemia under my care, this fever ultimately took on the characters of the Pel-Ebstein type of Hodgkin's disease.

With reference to the relation of the haemolysis to the megakaryoblastic marrow, I cannot satisfy myself that the haemolysis is simply due to the presence of immature cells in the circulation, these being more vulnerable and so readily dealt with by the normal haemolytic apparatus. There are cases of profound anaemia of the so-called secondary anaemia type where similar immature cells are in the circulation, and in which no such haemolysis occurs. And so, while the immaturity of the red corpuscles may be one factor in the increased haemolysis of pernicious anaemia, I think the evidence favours the view that there is also a definite haemolytic agent present, which is not in most other anaemias, as well as in the normal individual. There is little evidence that this haemolytic substance acts directly on the red cells. It seems more probable that it acts by stimulating the normal phagocytic process in the spleen, marrow, and other tissues.

That the megakaryoblastic marrow is entirely due to the increased destruction of red cells also seems to me improbable. Formerly it was held that the megakaryoblastic marrow was the result of the great overactivity of the marrow, the type of cell becoming more primitive so that it multi-

pl's more rapidly. But in polycythæmia, where there is apparently a great demand for the production of red corpuscles (sometimes there being three times the normal number of red cells in the circulation, and thus over a period of many years), there is no megaloblastic marrow. The same applies to acholuric jaundice where judging from the amount of bile pigment in the blood, the haemolysis must be at least as great as in pernicious anaemia. It must be remembered also that there is presumably a megaloblastic marrow in the earliest recognizable stage of pernicious anaemia at a time when there is very little anaemia of any sort. This is perhaps best seen in cases of acute combined degeneration of the cord, where with an anaemia of not more than is represented by 80 per cent of corpuscles, the blood is megalocytic in character. Consequently, the change from a normal to a megaloblastic marrow, which occurs, at least to some extent, when the patient has his remission, is of importance in this connection for it apparently must be initiated in many cases when the anaemia is still very profound, and a high degree of need for red corpuscles. It would seem that the megaloblastic change in marrow is more or less an initial change, produced possibly by the toxin which determines the increased haemolysis.

The following clinical details are of interest in this connection.

In a patient with polycythæmia who has been under observation for the past five years the red corpuscles ranged at first from 15 million per cubic millimetre, but under treatment with iron the number was reduced to 61 million. He took blood transfusion doses for four years and seemed to get on fairly well. He was reported again early in May 1927 he had been having drug treatment for about a year and the red cells were now 11 million. He was given phenyl hydrazine 4 grains daily and 14 days later the dose was increased to 8 grains. In three weeks time the red corpuscles had fallen to 4½ million with a colour index of 1.0. The films now showed the appearance of megaloblastic anaemia of moderate degree. The drug was then stopped and the megalocytes gradually lessened in number. On resuming treatment with smaller doses the megalocytes seemed to become more evident again. There was practically no bile pigment in the blood during treatment as shown by the van den Bergh test. Before treatment the serum was estimated at 1 unit and during treatment it did not rise higher than 1.2 unit. Before treatment the tests for urobilinogen and urobilinogen in the urine were negative and during treatment there were never more than faintly positive.

This case, in conjunction with the observations quoted above, seems to suggest that in certain toxic states there is an inhibition of normoblastic marrow with a corresponding anaemia, and that the megaloblastic marrow is consequent on or associated with this inhibition. The period of improvement in pernicious anaemia would thus be due to the withdrawal for the time being of the toxin which causes the disease. We know that the blood-forming organs are very sensitive to stimuli of one sort or another as illustrated by the leucopenia and the different forms of leucocytosis—polynuclear, eosinophile and mononuclear—which are met with in various morbid conditions. In pernicious anaemia the white cells are affected in this way but not the red cells. Certain other organs are readily disturbed by toxins, for example, the thyroid gland will hypertrophy or such stimulus, and sometimes this hypertrophy is an abnormal one—as for instance, in Graves's disease. A somewhat analogous to this occurs possibly in the marrow in pernicious anaemia.

It has also been suggested that this megaloblastic transformation in the marrow is the primary event in pernicious anaemia, the megaloblasts replacing the normoblasts much in the same way as the myeloblasts and myelocytes replace the erythroblastic marrow in leukaemia. I do not think this explanation helps us much, other than by suggesting an analogy, for we do not know the cause or the nature of leukaemia, whether leukaemia is regarded as neoplastic or hyperplastic in origin, there must be a stimulus of some sort producing such abnormal growth in the marrow. What that stimulus is remains a mystery. The fact that the extent and activity of the marrow varies greatly in different cases of pernicious anaemia, sometimes seeming almost aplastic and in other cases highly cellular, would seem unfavourable to this view of replacement of normal marrow as an initial event and so I think the evidence is rather in favour of inhibition

tion of normal marrow as primary, with megaloblasts in marrow as a secondary development.

In dealing with this megaloblastic reaction in pernicious anaemia I have spoken of it as being present in the bone marrow. But certain writers have described in the liver little intra-vascular areas which, they say, produce megaloblasts. They hold that these cells are formed locally, and are not simply convected there from the marrow by the blood stream. In other words they indicate that there is a return of the primitive blood formation in the liver, such as is met with in the embryo. Indeed, Piney seems to insist that in pernicious anaemia the liver is the only seat of origin for the true megaloblast, the large nucleated red cells formed in the marrow being what Nigeli called macroblasts—that is, cells as large as the megaloblast, but with a "cartwheel" nucleus and cytoplasm showing various degrees of polychromasia. These two cells are supposed to belong to different generations, the megaloblast representing the primary blood formation in the liver of the embryo, the macroblast the secondary formation of the bone marrow. The macroblast develops into the normoblast, but with the megaloblast there is no such relationship. Piney states that the large nucleated red cells found in experimental anaemias of the haemolytic type are macroblasts and not megaloblasts.

These views, if confirmed, open up a question of much interest in regard to the relation of the various cases of anaemia included under the symptom-complex pernicious anaemia but it is a matter for the skilled histologist rather than the physician. But in spite of such changes in the liver there exists in pernicious anaemia a marrow which we still call megaloblastic, and in which we find little groups of cells of primitive type—megaloblasts, megalocytes, and perhaps still more primitive cells, all cells such as are met with in the embryo. This marrow is not normoblastic and it presents one of the most constant and notable features in the pathological anatomy of pernicious anaemia. Such a marrow must be taken into account in discussing the pathogenesis of pernicious anaemia.

At the same time, I must emphasize the point that, since pernicious anaemia can be produced by several different toxins, so this megaloblastic marrow will be evolved in response to a variety of stimuli. There seems, too, no reason why there should not be lesser degrees of megaloblastic change without producing the complete picture of marrow and blood characteristic of pernicious anaemia. It is a question of inhibition of marrow there may be degrees of this inhibition, and degrees of megaloblastic response. In that way might be explained the profound secondary anaemias of long standing where at times there is a high colour index and megalocytes in the blood. In aplastic anaemia little areas of megaloblastic marrow have been noted *post mortem* in an otherwise aplastic marrow and a similar megaloblastic reaction has been found in the marrow of some patients dying of acholuric jaundice. I saw recently a woman, aged 34, who had been suffering from purpura of moderate severity for twelve years. The red cells numbered just over 1 million, with a colour index of 0.8, and there were numerous megalocytes and megaloblasts in the films, giving a picture more typical than in many cases of pernicious anaemia. The so-called pernicious anaemia of old age I think, can best be explained in this way. The following case illustrates this.

A man aged 78 complained of loss of strength and rheumatic pains for which he had been treated at Harrogate. His blood count was 70 per cent of the normal and had the characters of a secondary anaemia. Five weeks later and without obvious cause the red cell count had fallen to 1½ million with colour index 1.5. The films now presented the appearance of a typical pernicious anaemia. That is, I am unwilling to label a pernicious anaemia. I think it is more likely of the aplastic type.

Professor Gulland has said that pernicious anaemia is megaloblastic from the beginning and does not develop out of an anaemia of low colour index. But we so seldom have an opportunity of examining cases of pernicious anaemia in the initial phase of the disease that it is difficult to find evidence for or against that statement and so I record the following case.

A woman aged 31 was under observation in the hospital for three different periods in the course of two years. There was no obvious

cause for her anemia other than oral sepsis, which was pronounced, and perhaps poverty and ill feeding. When first examined the red cells were just under 2 million, with a colour index of 0.55, and the films gave the appearance of a secondary anemia. The patient was treated with iron, and in the course of the next ten days the red cells had increased to nearly 3 million, and the colour index was now 0.64. During the following six weeks the red cell count fell till it reached 1.1 million, the colour index being 1.6, and the films typically those of pernicious anemia. From that time onwards the course was that of pernicious anemia, with two periods of very marked improvement. She ultimately died with a count rather over half a million.

It is difficult to insist that this case, when first seen, was not pernicious anemia with a remission, but the age of the patient, the count of two million red cells and very low colour index, and the appearance of the films, were much more suggestive of a secondary anemia.

I have seen a number of cases of pernicious anemia associated with syphilis, but I could not satisfy myself that the syphilis was the causal agent in producing the anemia, for in none of the cases did antisyphilitic treatment produce a cure. In one case there was improvement coincident with the giving of mercury, but the patient about the same time had also a blood transfusion, and anyhow the anemia recurred and proved fatal some two or three months later. Mercury in this case did not seem to affect the course of the anemia to any material extent.

### III—TREATMENT OF PERNICIOUS (ADDISONIAN) ANAEMIA WITH A DIET RICH IN LIVER

BY

GEORGE R. MINOT, M.D.,

AND

WILLIAM P. MURPHY, M.D.,  
Boston, Massachusetts

SINCE Addison in 1849 first described under the title "idiopathic anemia" the disease now known as pernicious anemia or Addison's anemia, it has received much study and many forms of therapy have been advised. The spontaneous remissions of the disease and the bizarre course it often runs have made it notoriously difficult to determine accurately the effect of any procedure upon it. Even so, there has not occurred heretofore a prompt, rapid, and marked increase of the red blood corpuscles to a level of 4 million or more per cubic millimetre in essentially all cases following a given form of treatment. Our experience<sup>1,2,3,4</sup> with 125 cases of typical Addisonian pernicious anemia has taught us that this is made possible by the daily ingestion of large amounts (150 to 225 grams) of mammalian liver, together with an adequate well balanced diet. The 125 patients have been treated with the liver diet for from three months to three and a half years. The health of all has been distinctly improved. Not only has nearly every one of the patients responded promptly to the liver diet, but if they have continued to take it satisfactorily their red blood cell count has remained elevated, and in almost all instances above 4 million, and usually above 4.5 million, per cubic millimetre.

Liver was selected as a food that might benefit patients with pernicious anemia for various reasons. Among others it was chosen because we thought it might stimulate the maturation of the megakaryoblasts that crowd the bone marrow in aplasia. Peabody's<sup>5</sup> excellent studies upon the pathology of the bone marrow obtained by puncture indicate that liver feeding probably does act in this manner. We have shown<sup>6</sup> that after feeding with large amounts of liver there occurs with extraordinary regularity a prompt temporary, often marked increase of the young red blood cells (reticulocytes). This behaviour of the reticulocytes also suggests that liver stimulates the maturation of the megakaryoblasts. Approximately the reticulocyte increase is inversely proportional to the height of the red blood cell count. This is to be expected because there are fewer megakaryoblasts in the marrow when the count is relatively high than low. When the count is about 1 million per

cubic millimetre the reticulocytes start to rise (from a level about 1 per cent of all the red blood cells) in from three to six days after eating an adequate amount of liver. The peak of their rise occurs a few days later, reaching often 15 per cent and sometimes above 40 per cent. By the end of about sixteen days these cells usually have returned close to their normal percentage. When the red blood cell count is about 3 million per cubic millimetre the reticulocytes rise only a few per cent. The increase is much about, and then only in special circumstances.

The beneficial effect of eating liver can hardly be attributed to stopping a hemolytic process. It has seemed to us that the dysfunction of haemoglobin pigment metabolism is a secondary phenomenon, and that the anemia is primarily not due to a hemolytic process, but to a defect in the manufacture of the red blood corpuscles.

The nature of the material effective in pernicious anemia is being investigated by studying the influence of giving fractions of liver. Dr. Edwin J. Cohn has isolated an effective fraction, and with him and our associates we have made preliminary reports concerning it.<sup>7,8</sup> This fraction represents about 1 per cent of the liver. It contains nitrogen, but is non-protein in nature, is precipitated by alcohol, and soluble in water. The indications at present are that its effect is not due to known vitamin. A few grams of the purest fraction taken daily by mouth as a powder or in an aqueous solution is followed by a prompt and marked increase of reticulocytes and a rapid rise of the red blood corpuscles, and in a similar manner is as beneficial to patients with pernicious anemia as whole liver. This has been the effect in twenty patients treated recently with a potent fraction, including two in whom the disease was so far advanced that they were in a comatose condition when treatment was begun. Only two other patients have been given an effective fraction, and these were in a state of coma and died within four days after the treatment was started. During the time of our studies West<sup>9</sup> has also obtained a potent fraction. Knowledge of the precise nature of the effective material which appears to act in a rather specific manner, may lead to a better understanding of the mechanisms of the disease.

The details concerning the effect and use of the liver fraction will be presented at a later date, but summarized statements concerning the 125 patients treated with the liver diet are given. There has been little difference in the rate at which the red blood corpuscles rose or the level they reached when the diet was started in a first relapse or a subsequent one. The increase of reticulocytes occurs before there is a definite rise in the red blood corpuscle count.

Table showing the Rate of Increase of the Corpuscles for all of the 108 of the 125 Patients whose Red Blood Cells rose below 1.5 million per cubic millimetre when they were first placed on the Liver Diet—no matter whether they took it well or poorly

Time of Observation	Average Red Blood Cell Count in million per cubic millimetre
Before diet begun	1.50
After diet taken about one month	3.36
After diet taken about two months	4.10
After diet taken from four to six months	4.45

Accompanying the rise of corpuscles the excess of heme pigments in the plasma rapidly decreased so that after within three weeks the icterus-index has become less than commonly observed in normal people. Macrocytosis of the red blood cells decreased as the counts rose, so that the average diameter of the cells often has become normal and sometimes smaller.<sup>10</sup> Furthermore, as the red blood cell counts rose to over four million per cubic millimetre and haemoglobin approached normal, the colour index frequently became less than one and sometimes below normal.

The red blood cells of 119 patients have reached 4 million or more. They have remained at or above this level except for temporary, seldom marked drops in about 15 per cent of the cases. The decreases were not

<sup>1</sup> From the Medical Service of the Collis P. Huntington Memorial Hospital of Harvard University; the Medical Clinic of the Peter Bent Brigham Hospital, and the Department of Medicine of the Harvard Medical School.

always associated with a partial or complete omission of the prescribed amount of liver. Failure to take a sufficient amount of liver or the presence of a complication, such as an infectious process, may cause the count to fall, or may cause it to rise less rapidly than might be expected. Damage to the bone marrow from multiple transfusions of blood may be a reason for an unsatisfactory response to liver feeding.

The health of the six patients whose counts have not reached 4 million per cubic millimetre has been distinctly improved. In at least three the count has not risen above about 3.5 million per cubic millimetre because the patients have not taken the liver diet satisfactorily. In the other three, probably because of complications, the count has risen unusually slowly and only to about 3.75 million in two and 3.3 million per cubic millimetre in the other. Experience with patients who have responded slowly indicates the importance of perseverance and the desirability of forcing large amounts of liver for months, 100 grams a day may produce rapid improvement, but double this amount is more apt to do so.

The ultimate effect on patients of continuing to take liver, or something contained in it together with an adequate diet can only be determined in the future but it has already been ascertained that the benefit derived from such treatment is not limited to a few months.

At the end of a year the average red blood cell count for all of the 60 patients who have taken the diet for this length of time was 4.52 million per cubic millimetre. This includes the counts for 8 who took the diet unsatisfactorily, particularly because they were not advised to eat a sufficient amount of liver, being among the first patients treated. Eighteen of the patients have taken the diet for two years or longer, 3 of whom have done so for three years. At two years the average count was 4.65 and at three years 4.81 million per cubic millimetre. These high average counts have been persistently maintained, and the average for the patients who have taken the diet particularly satisfactorily is even higher. At any given time after the patients had taken the diet for three months the counts of over one third, including those taking it poorly, have been 5 million or more per cubic millimetre.

The symptomatic improvement is usually rapid and striking. It is often evident in a few days or before a definite rise in the red blood cells can be demonstrated. As a rule the patients have felt and appeared well, except for disorders of the central nervous system two months after starting the diet. The appetite has improved rapidly and often become ravenous. Gastro-intestinal symptoms have decreased quickly. Tongue symptoms usually vanished soon after liver was first taken and have not recurred in patients who have continued to take the diet well. The tongue has frequently become normal in appearance. Achlorhydria, however, has persisted in the 20 cases examined. Symptoms referable to the neural system have not definitely progressed or developed under adequate dietary therapy. Numbness has disappeared often and occasionally bone vibration sense has increased. Of course, altered reflexes persist, but co-ordination of the extremities has improved frequently. This decrease of neural symptoms has often been gratifying to the patient. It is reasonable to attribute the greater part of such improvement to increase of muscular strength secondary to the continuous high level of the red blood corpuscles. Exercises to restrain and develop muscles are helpful for these patients.

It will require often much time, tact and sympathy to persuade the patient to take the correct food. Giving little other food than liver—by stomach tube if necessary—has enabled individuals soon to take the full amount (150 to 225+ grams cooked weight) and an adequate diet. Patients able to take more than 200 grams of liver a day may regain health faster than if less than this amount is taken. Cooked liver may be served in any way that pleases the patient, but prolonged boiling is to be avoided. The broth in large amounts is efficacious. Raw liver served as a finely divided pulp has been found particularly suitable. Many patients have preferred this to cooked liver

because it is simple to take and can be swallowed rapidly. One hundred and eighty grams of the pulp (about equal to a similar amount of cooked liver) a day, divided into two portions, and taken mixed with orange juice or water mid morning and mid afternoon, is recommended. The juice pressed from raw liver is effective if taken in large amounts. The possibility of parasitic infection is to be recognized but seems remote.

The problem of how much liver the patient should continue to eat after his red blood corpuscle count has become normal remains unsolved. In some cases as little as 150 grams three times a week has apparently been sufficient. There is evidence, however, that some patients require more liver than others to keep them as well as possible. The necessity of prolonged continuation of liver or a fraction of it is emphasized.

It is advised that the diet be rich in fruits and green vegetables and that it contain red meat. No unusual amount of protein or number of calories are necessary. Excess of fat has not inhibited a rapid growth of the blood cells but in large amounts it may upset digestion and cause undesirable gain in weight. For these reasons and some theoretical ones large amounts should be avoided.

It is desirable to curtail sweet foods and those rich in starch, especially sugary ones. Such food has no favourable effect on blood formation and often intensifies the colic on which frequently occurs in pernicious anaemia. The diet for each patient should be prescribed for that person, and must contain large amounts of liver, or its equivalent, and foods which will supply liberally but not excessively, all requirements of the body. Treatment other than dietary and the administration of a preparation of liver is subsidiary.

A diet rich in liver may benefit patients other than those with pernicious anaemia, but it is not effective in all anaemias. This topic, however, is not pertinent to the present discussion.

Although administration of liver to patients very ill with pernicious anaemia has often been followed by rapid improvement in some far advanced cases death may occur within a few days after treatment is begun, before sufficient time has elapsed for the ingestion and potent action of an adequate amount of liver or liver fraction. It is highly probable that if a patient supposed to have pernicious anaemia has shown no improvement after taking liver in adequate amounts for about four weeks the diagnosis has been incorrect. Our experience appears to justify the assertion that if the therapy described is properly carried out a great improvement in health follows in practically all patients with pernicious anaemia.

#### SUMMARY

The study of 125 cases of pernicious anaemia treated with regularity for from three months to three and a half years with a diet rich in liver (180+ grams daily) indicates that practically all patients with this disease are benefited, usually markedly and promptly. In almost all instances the red blood cell count has risen above 4 million per cubic millimetre and if the diet has been taken continuously and satisfactorily the counts have remained above this level to the present time.

Recent studies with Dr Edwin J. Cohn indicate that the ingestion of but a few grams a day of a certain non-protein fraction of liver acts in pernicious anaemia with apparent specificity, as does whole liver. This fraction increases the red blood cells of these patients promptly and rapidly. The use of such a liver fraction should simplify treatment. Even if the patients must take an adequate, well balanced diet.

#### IV—THE PATHOGENESIS, PROPHYLAXIS, AND TREATMENT OF PERNICIOUS ANAEMIA

BY

ARTHUR F. HURST, M.D., F.R.C.P.,  
Physician to Guy's Hospital

##### PATHOGENESIS

In a discussion on Addison's anaemia (A.A.) subacute combined degeneration of the spinal cord (S.C.D.) should also be considered, as signs or symptoms of the latter appear sooner or later in about 85 per cent of cases of A.A., and some degree of A.A. almost invariably appears during the course of S.C.D. Since the haemoglobin percentage may be 90 or even 100 in well developed S.C.D., cases of the latter afford admirable controls, such as Professor Gulland required, for the investigation of the achlorhydria and intestinal bacteriology in the pre-anaemic stage of A.A. In 53 out of 54 cases of A.A. and in all of 33 cases of S.C.D. in the Medico-Neurological Clinic at Guy's Hospital and in New Lodge Clinic since 1921, achlorhydria was present, and the collected results of other investigators give something like 99 per cent as the frequency of achlorhydria in A.A. This is in striking contrast with carcinoma of the stomach, in which achlorhydria was only present in 59 per cent of my 32 cases. Moreover, it is present at the very earliest stages of A.A. and S.C.D., and 22 cases have now been recorded in which achlorhydria was known to have existed for one to twenty-five years before the onset of symptoms, whereas in cancer of the stomach, as in tuberculosis, the development of achlorhydria can be watched as the disease progresses.

I believe that the absence of hydrochloric acid from the gastric secretion is the one essential predisposing cause of A.A. and S.C.D., and that the cause of the achlorhydria is immaterial. The most common cause is probably constitutional achylia gastrica, an inborn error of secretion, which is often familial. Thus in 12 out of 43 private cases of A.A. (28 per cent) of my own, and in 65 cases recorded by others, there was a history of A.A. in one or more members of the family in one, two, or three generations. In 3 of my cases of S.C.D. and in 3 other recorded cases one or more other members of the family had had A.A. Still more conclusive are the 6 cases of my own and 26 others, in which achylia gastrica without A.A. or S.C.D. was present in other members of the family of patients with A.A., in 5 of these more than one member had A.A., and in 1, different members of the family had S.C.D., A.A., and achylia.

In 6 of my 43 private cases there was a clear history of acute gastritis, which had led to the achlorhydria, and I have seen 3 others in which the chronic alcoholic gastritis so often associated with cirrhosis of the liver was the cause. Like Professor Gulland, I have only seen 2 cases of A.A. associated with cancer of the stomach, but the rarity of this is due to the achlorhydria being secondary to a rapidly fatal disease, so that there is generally insufficient time for A.A. or S.C.D. to develop. Very significant are the 3 cases of achlorhydria after gastro-enterostomy and the 4 of achylia following complete gastrectomy, in which A.A. or S.C.D. followed after an interval of from one to ten years.

The achlorhydria does not only act as I believed at first, by allowing the small intestine to become infected with swallowed streptococci derived from infected teeth, tonsils, or nasal sinuses. For Knott has recently shown that the abnormally alkaline contents of the small intestines in achlorhydria form a particularly good culture medium, so that in addition to the streptococci, which reach the duodenum from above owing to the loss of the

acid antiseptic barrier of the stomach, *B. coli* invade it from the colon. In 37 of my cases of A.A. and S.C.D. Knott found that the duodenal contents, which were sterile or almost sterile in over 400 controls with normal gastric acidity, gave cultures of *B. coli* in 94 per cent of cases and streptococci in 97 per cent, and that one or both of these were haemolytic in 90 per cent of cases. Staphylococci, which were rarely haemolytic, were found in 44 per cent of cases, and anaerobes, but not *B. welchii*, were often present, possibly the latter would be found in excess in the lower parts of the small intestines. Our conclusion is that any haemolytic organism which invades the small intestines owing to the presence of achlorhydria may give rise to A.A., but probably the associated neurotoxin which produces S.C.D. is the product of a specific bacterium.

##### PROPHYLAXIS AND EARLY TREATMENT

Prophylactic measures should be taken in all patients in whom achlorhydria is found in the course of a routine investigation of some digestive disorder, achlorhydria is present in no fewer than 150 out of 1,000 consecutive patients who were given fractional test meals at New Lodge Clinic. Not only does elimination of dental and nasopharyngeal sepsis and the constant use of hydrochloric acid generally cure or improve their digestive symptoms, but it also removes the danger, however remote this may be, of the later development of A.A. and S.C.D. I think, too, that the near relatives of patients with A.A. and S.C.D. would be wise to have test meals, and to take acid for the rest of their lives if they are found to have achylia.

Early treatment entails early diagnosis. It is time that all pathologists realized that the one essential feature in the blood picture of A.A. is megalocytosis, this often precedes actual anaemia and may persist after recovery from it. I often see private patients with severe A.A. in whom a correct clinical diagnosis, made by the general practitioner many months before, had been rejected because the blood picture did not conform with the pathologist's idea of A.A., which is too often derived from the examination of cases in the most advanced stages.

It should be remembered that the commonest cause of persistent paraesthesia of the feet and hands is S.C.D., and that this may be present for a considerable time before any physical signs of nervous disease appear. The symptoms should at once suggest the desirability of giving a test meal and examining the blood, the presence of achlorhydria, which we found in only 1 out of 25 cases of disseminated sclerosis and tabes (that is, the frequency as in normal individuals), would strongly point to a diagnosis of S.C.D., the probability of which could be greatly strengthened by the discovery of megalocytosis with or without reticulocytosis.

I wish also to draw attention to the great importance of the characteristic glossitis described by William Hunter, as this is frequently the first symptom of the disease. I have been consulted by 3 patients and passed by 2 on account of a sore tongue, in whom achlorhydria and very early A.A. were discovered on further investigation. Most patients with glossitis consult first their general practitioner and then their dentist after that they may consult a surgeon or a dermatologist. It is to these members of the profession that we must look for early diagnosis in such patients, they have in the past escaped recognition until months or even years later, when the disease was well advanced. A German dermatologist, Heyn, was specially interested in the condition, and recognized 20 cases of Hunter's glossitis. All had achlorhydria, and 39 per cent gave evidence of the presence of A.A. on more careful investigation. Within five years no less than 55 per cent more had developed the disease and 21 per cent showed suspicious signs, leaving a single case in which the glossitis and achlorhydria were still the only symptoms.

If S.C.D. were more often diagnosed before the presence of abnormal physical signs and if all patients with suspicious glossitis had their gastric contents and blood examined, it should be possible to cure the disease in many patients in its very earliest stages.

## TREATMENT

The first essential in treatment is to remove the cause. All foci of infection in the mouth, throat and nose should be eradicated as completely as possible—but very gradually and only after preliminary autogenous vaccination as otherwise severe haemolytic or neurotoxic reactions may occur. The achlorhydria should be treated by the administration of large doses of dilute hydrochloric acid. If properly prepared a beverage containing 2 drachms of dilute hydrochloric acid in about 12 oz of water is so palatable that I have never found a patient unwilling to drink it regularly three times a day. The following printed instructions are given to patients for preparing the acid drink; it is sometimes necessary to begin with 1 drachm and gradually increase to the full dose of 2 drachms.

*Instructions for taking Hydrochloric Acid*

Add two tea-spoonfuls of the acid to about half a pint of water to which the juice and pulp of an orange and some sugar have been added. This should be drunk fasting in the morning one hour before breakfast, the same quantity of the same strength should be taken as a beverage with lunch and again with dinner. To the latter two a small spoonful of pepin should be added.

Lemon or other fruit juice can be substituted for orange for a change or syrup of grenadine without the addition of sugar. A little wine can be added to the mixture. The simple addition of sugar without fruit juice is sufficient, but is generally less palatable. Barley water or cider may be substituted for orangeade or lemonade.

*Tea orangeade*, an effervescent orange drink with a tea-spoonful of acid to each 6 ounces can be obtained in syphons from Messrs. Alcock and Hobart.

In order to prevent any deleterious action of the acid on the teeth the mouth should be thoroughly washed as soon as possible with water in which a little sodium bicarbonate may be dissolved. Alternatively a second tumbler containing water should be provided at lunch and dinner so that a small mouthful can be taken immediately to wash away the acid every time some of it has been drunk.

Lastly a vaccine prepared from the bacteria isolated from the duodenum—not a stock vaccine nor one prepared from the stools which rarely contain the organisms found in the duodenum—should be given but the dose should at first be small, and it should only be very slowly increased so as to avoid any reaction.

The anaemia requires treatment by transfusion, arsenic and diet. I first tried the liver diet after reading the experimental work of Robbins and Whipple in 1925 but the amount I gave was quite insufficient. The remarkable results obtained by Muot have been fully confirmed in my own experience since I have given the large quantity of liver recommended by him. My impression is that many patients now get well who formerly would have died before the other treatment of the intestinal infection had time to be effective so that it should in the future be possible to cure the vast majority of cases by a combination of causal treatment with liver diet. The good effect of the liver soup which has for many years been given to patients with sprue many of whom suffer from a form of anaemia very similar to A A, is doubtless due to its specific action on the anaemia.

I believe that what is generally regarded as a remission of A A is often really recovery, but as the conditions are still present which led to the first attack, a new attack is almost certain to occur unless the exciting causes are removed. Hence it is essential to see that the mouth and nasopharynx are kept free from sepsis and that hydrochloric acid should be taken continuously for the rest of the patient's life, however well he may be and however long he may remain free from symptoms except in the very rare cases of which I have only seen one example—in which the achlorhydria is due to gastritis, the treatment of which is followed by a return of normal gastric secretion. The future will show whether it is also advisable to continue permanently with the liver diet.

I think it is clear that we know more about the pathogenesis of A A and that the results of treatment are more hopeful than might be assumed from the opening address of the President of the Section.

## DISCUSSION

PROFESSOR VAN DEN BIEREN (Utrecht) emphasized the importance of achlorhydria since with few exceptions the presence of hydrochloric acid excluded a diagnosis of pernicious anaemia. He had observed that a great number

of the red cells in pernicious anaemia were elliptical in shape a condition which he had not found in marked degree in any other disease. Another point of importance was the bilirubin content of the serum which was nearly always increased in pernicious anaemia. They would agree that a great increase in the haemolysis was the basic pathological event. By the word haemolysis was meant not a humoral haemolysis, but a cellular destruction of the red corpuscles with a breakdown of the haemoglobin molecule; it was this that gave rise to the abnormal bilirubin content of the serum, urobilinuria and in severe cases to the presence of haematin in the blood. He had demonstrated long ago that the spleen was the site of blood destruction, his experiments showing that blood from the splenic vein was richer in bilirubin than blood from the splenic artery or peripheral blood. He suggested that a microbial cause of the true cryptogenic Addisonian anaemia would be more likely to be found among the protozoa than among the bacterial micro-organisms the long course the relapses and remissions the moderate pyrexia the leucopenia and the response—albeit temporary—to arsenic all seemed to him features common to protozoal infections.

DR. IRON SCHIFF (Cincinnati) said that it was generally agreed that bile pigment was formed from haemoglobin chiefly in the bone marrow also in the spleen and to the least extent in the liver the function of the liver was chiefly one of excretion. In pernicious anaemia the bilirubin content of the serum was greatest during the active stages with a low red cell count and low haemoglobin percentage and it decreased during remission with a rise in the red cells and haemoglobin. This was, in his experience in sharp contrast with the findings in secondary anaemia. In the Cincinnati General Hospital they had found that those patients with enlarged spleen tended to have a higher bilirubin serum content than those without splenomegaly. He recalled the observations of Brown, Ames, Warren and Peabody, that following blood transfusion in pernicious anaemia there was a fall in the serum bilirubin which, contrary to what happened in spontaneous remissions, might be unaccompanied by evidence of increased bone-marrow activity.

DR. W. E. COOKER (Wigan) confined his remarks to the polymorphonuclear leucocyte as he believed that an alteration of this cell led directly to the primary etiological factor in pernicious anaemia. The leucocyte was derived from the haemocyctoblast which was also the parent of the secondary erythroblast and the megakaryocyte. In the marrow the polymorph cell had a single lobed nucleus, in the blood stream the nucleus became more lobed as its age increased. He divided the cells into five classes according to the number of lobes in the nucleus: class 5 containing all cells with five or more lobes. In infections the older cells died out, and there was a great increase in classes 1 and 2 this was a constant finding in microbial infections, but in pernicious anaemia the opposite occurred and there was an increase in classes 4 and 5. Polymorph cells with more than five lobes were rare in normal blood and except as macrophages never occurred in infective states, in pernicious anaemia they were common. The explanation of this phenomenon he believed to be that the cell was endowed with an abnormal life by inheritance from its parent the haemocyctoblast. This view was supported by the presence of leucocyte which did not conform to any normal type. There were two types of giants—one an enlarged edition of the polymorph occasionally found also in acute infections and in carcinoma the other of megakaryocyte type found only in pernicious anaemia, and corresponding in size and nuclear conformation to the megakaryocyte of the marrow. In the terminal stages of pernicious anaemia this type was sometimes very numerous. The only explanation covering the facts was that the haemocyctoblast as the result of change in the environment or of inherent reversion to an ancestral type gave to some myeloblasts a duplex biophore which resulted in a hybrid cell type. Polymorphocyte it has was leucocyte or the megakaryocyte type if it has was megakaryocyte. The question whether the old blood megakaryoblast and the megakaryocyte type of macrophocyte were endodermal or

mesodermal in origin or, conversely, whether they were produced in marrow, liver, or other haemopoietic organs, did not affect the argument that the primary etiological factor in pernicious anaemia was in the haemocytoblast

Dr STANLEY DAVIDSON (Edinburgh) criticized Dr Huist's observations on the bacteriological side. He was not surprised that Dr Huist had never found *B. welchii* in cultures from the duodenum, since the alkalinity of the upper part of the small intestine was most unfavourable for the growth of that organism, nevertheless, he had himself obtained it twice in that situation in cases of pernicious anaemia. In the large intestine, however, *B. welchii* was always present in enormously increased numbers in cases of pernicious anaemia, and although other organisms, such as streptococci, were also present in greatly increased numbers, the increase in *B. welchii* was always considerably larger. He also gave a brief summary of some unpublished results of Torrey and Kohn, who had produced a typical pernicious anaemia in monkeys by means of a *B. welchii* infection.

Dr SALISBURY SHARPE (London) said that he had been firmly convinced for some years that pernicious anaemia was a spirochaetral disease. Two Addisonian anaemias had all the characteristics of a protozoal, and especially of a spirochaetral, disease. In support of this suggestion, Osler had noted the occurrence of fever, the remarkable remissions, the nervous lesions, and the value of arsenic in treatment, to these he would add certain characters of the blood picture which occurred in other protozoal diseases, such as relative lymphocytosis, the occurrence of megalocytes and "ghosts," and the usually late onset. According to McEwen, spirochaetes had been observed in the blood in cases of pernicious anaemia.

## NEUROLOGICAL AND MECHANICAL FACTORS UNDERLYING IMMOBILITY OF THE VOCAL CORDS

### I—THE NEUROLOGICAL ASPECT

BY

A BROWN KELLY, M.D. F.R.F.P.S. GLAS

Consulting Surgeon for Diseases of the Throat and Nose, Victoria Infirmary, Glasgow

IMMOBILITY of a vocal cord is a danger signal which should at once arouse in us a keen sense of responsibility. Occasionally it is the result of a morbid process which has become quiescent, oftener it is an early manifestation of grave disease. Our first aim is to discover the cause or, in many cases, "to know the worst," so that we may be in a position to form an opinion as to the patient's future outlook, to offer advice as to how he should live, and to suggest suitable treatment. Although this discussion is to include the prognosis and treatment of the conditions giving rise to immobility of the vocal cords, I intend to devote all the time at my disposal to the problems of diagnosis.

The immobility of a cord may be due to fixation produced by mechanical factors or to paralysis. Mr Herbert Tilley has undertaken to deal with the subject from its mechanical side, my duty is to present its neurological aspect.

In order to determine the etiology of a case of paralysis of one or both cords it may be necessary to pass in review the lesions to which the laryngeal motor nerve supply is liable at different levels between its origins in the cortical and bulbar centres and its endings in the larynx. I shall make a brief survey of this kind, beginning with the nerve centres.

#### The Cortical and Bulbar Laryngeal Centres

The larynx subserves two great functions—namely, respiration and phonation—each of which is represented by bilateral centres in the cortex and medulla. The chief respiratory nerve centres are seated in the medulla, and

their activity is manifested in the larynx by the tonicity of the abductors, whereby the vocal cords are kept in or near the respiratory position. By means of the subordinate respiratory centres in the cortex further slight abduction can be effected at will, as on deep inspiration.

The principal phonation centres are cortical, and the less important are bulbar. Stimulation of the phonatory cortical centre in either hemisphere produces bilateral symmetrical adduction of the vocal cords. When the cortical centres on both sides are destroyed the vocal cords continue their respiratory movements, but the animal has no control over these, so that volitional phonation is lost. Complete paralysis of a vocal cord cannot, therefore, be produced by a cortical lesion.

#### Laryngeal Paralysis of Cerebral Origin

How, then, are we to account for the fairly numerous cases on record in which cerebral disease was regarded as the cause of a laryngeal paralysis? The main objection to recognizing this relation has been the incompleteness of the examination. In order to establish the alleged connection it is not sufficient to diagnose during life paralysis of a vocal cord and to find after death a lesion of the cortical centre of phonation. One must be able to exclude the presence of disease in the medulla, vagospinal and recurrent nerves, and muscles of the larynx, to any of which conditions the vocal cord paralysis may be due.

Broeckert, who studied this question with great care, expressed the opinion that laryngeal affections of cortical origin would cease to be rare when, instead of looking for paralysis of a cord, we search systematically for the slightest alteration in mobility or sensation in the larynx, and for functional disturbances in articulation and voice production.

#### Laryngeal Paralysis of Bulbar Origin

Disease in the medulla may be limited to a small area of the laryngeal centres so that only one muscle is affected—for example, the abductor. As the morbid process advances the centres for the adductors and tensor, and those controlling other branches of the vagospinal and adjacent cranial nerves, may be successively involved on one or both sides. On the other hand, pathological changes in the laryngeal centres may be secondary to those in neighbouring centres.

The chief diseases of the medulla which, by involvement of the laryngeal centres, give rise to immobility of the vocal cords, are tabes, progressive bulbar paralysis, syphilis, arteritis and gummatous, syringobulbia, disseminated sclerosis, and haemorrhages and softening from thrombosis and embolism.

Laryngeal paralysis is met with in about 40 per cent of cases of tabes. The paralysis, almost invariably adductory (Burger), may be the first sign. The diagnosis is aided by the association of laryngeal crises.

#### Lesions of the Roots

The roots of any or all of the last four cranial nerves are liable to be damaged simultaneously or successively by meningitis, fractures at the base, abscess, tumour, aneurysms, etc. Gummatous and tabes are the common causes.

#### Associated Paralysis

Owing to the close grouping of the centres and roots of the ninth, tenth, eleventh, and twelfth cranial nerves and of the trunks of the ninth, tenth, and eleventh nerves for a short distance below the jugular foramen, damage or injury of one is liable to implicate one or more of the others, and thus give rise to an associated paralysis. In knowledge of the commoner varieties may be of assistance in determining the exact site of the nerve lesion producing immobility of a vocal cord. Associated paralysis is comparatively rare in civil life, but was not infrequently met with during the war in the wounded sent home. An extraordinary feature in these cases was the proximity of the path of the projectile to large vessels, injury to which would have immediately proved fatal.

In discussing the syndromes arising from the laryngeal associated paralysis it is convenient to regard the purely sensory and the spinal accessory as entire

\* Report of a discussion in the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association at Edinburgh. Mr A. Logan Turner, F.R.C.S. Ed., President of the Section, was in the chair.

In the undernoted associated paralyses the vagus may or may not be implicated. A lesion when present gives rise to symptoms indicating either excitation (hyperaesthesia) of the larynx, cough, acceleration of respiration (etc.) or inhibition (anæsthesia or hypæsthesia of the palatal, pharyngeal, and laryngeal mucous membranes, and slowing or difficulty of respiration).

*Paralysis of the spinal accessory and glossopharyngeal (ninth and tenth).—*These nerves, with the vagus, pass through the jugular foramen together, and a lesion involving them gives rise to the syndrome of Veret which is characterized by laryngeal palatal pharyngeal, and shoulder girdle (sterno-mastoid and trapezius) paralysis. The chief distinguishing features of the syndrome are due to involvement of the glossopharyngeal, in consequence of which taste at the back of the tongue is blunted or abolished (best tested by a solution of quinine) and the posterior wall of the pharynx is seen during phonation or retching to glide horizontally towards the healthy side ("curtain movement" of Veret). A vocal cord paralysis associated with signs of implication of the ninth nerve may therefore be regarded as due to a cause seated in or above the jugular foramen, for on emerging from this the ninth passes away from the vagus.

*Paralysis of the internal and external branches of the spinal accessory (eleventh complete)* is due to a lesion situated at or above the base of the skull but unlikely to be at a lower level as the external branch on emerging from the jugular foramen leaves the vagus and passes to the sterno-mastoid and trapezius. A non-lateral laryngeal palatal, and shoulder girdle paralysis (syndrome of Schmidt) results.

*Paralysis of the internal branch of the spinal accessory (eleventh incomplete)* is due to a lesion above the origin of the pharyngeal branch. It is characterized by paralysis of a vocal cord and the corresponding half of the palate (syndrome of Arellis).

*Paralysis of the spinal accessory below the origin of its pharyngeal branch and of the hypoglossal (eleventh and twelfth).—*A lesion may involve these two trunks when close together below the lower ganglion of the vagus. A glossopharyngeal paralysis results (syndrome of Tapia). In several cases the wound is produced behind the ascending process of the lower jaw by the goring of a bull or by a dagger.

*Paralysis of the spinal accessory above the origin of the pharyngeal branch, and of the hypoglossal (eleventh and twelfth)* gives rise to paralysis of the palate in addition to that of the larynx and tongue (syndrome of Hughlings Jackson). The shoulder girdle may or may not be involved.

*Paralysis of the four lost nerves (Collet-Sicard syndrome)* is rarely encountered.

*Paralysis of the sympathetic eighth, seventh and sixth nerves* may be associated individually or in any combination with any of the syndromes.

#### The Thyroid Gland

Vocal cord paralysis may be caused by disease of the thyroid or by operation for its removal.

Enlargement of the gland can readily damage one of the recurrent nerves by pressure, traction, torsion or ulceration. The pressure affecting the nerve is usually exercised by the postero-mesial angle of the growth. Bilateral paralysis almost invariably denotes a malignant thyroid. A goitre which is small and hard or sits on the trachea is capable of doing more injury than one which is large and soft or situated further from the middle line. In consequence of displacement of the trachea the nerve implicated may be on the opposite side to that of the enlarged or larger lobe. Damage to a recurrent nerve is more apt to be caused by an intrathoracic than by a cervical goitre. The left recurrent nerve, owing to its longer and more exposed course is oftener affected than the right.

The paralysis commonly produced by a goitre is the unilateral abductor variety, and as this does not give rise to obvious symptoms it readily escapes notice unless the larynx is examined. The onset is usually gradual but may be sudden as when bleeding takes place into a large cyst in the goitre. Complete recurrent paralysis with loss of voice

is occasionally caused by a break in the continuity of the inferior laryngeal nerve—for example from ulceration.

Dyspnoea, which is the commonest symptom of an enlarged thyroid is generally produced by narrowing of the trachea from pressure of the gland. Slight shortness of breath on exertion may also be due to narrowing of the glottis from unilateral abductor paralysis. When the paralysis is bilateral the dyspnoea is pronounced and the obstruction is evident on laryngoscopic examination. In some cases of goitre in which sudden death has taken place the cause would appear to have been suffocation following spasm of the glottis (Berry).

The percentage of cases of goitre in which pre-operative laryngeal examination revealed vocal cord paralysis has been estimated by several surgeons. J. M. Welch considers 10 per cent as approximately correct. In the Jackson Clinic Barlow noted 6 per cent in 300 patients. A. S. Jackson states that in 15 per cent of intrathoracic cases unilateral paralysis is found and in 462 similar cases in the Mayo Clinic partial or complete paralysis of one or both cords was noted in 10 per cent but hoarseness in only 29 instances.

Operation on the goitre has an uncertain effect on the paralyzed cord. The longer the paralysis has been present the less likely the recovery. After operation on the thyroid the patient may be slightly husky or even aphonic for a few days owing to transient partial or complete paralysis following traction or undue compression of the nerve. On the other hand the voice may be normal after the operation, but subsequent cicatricial contraction of the tissues in the vicinity of the nerve may lead to a vocal cord paralysis. This may occur although the nerve has not been damaged by the surgeon. Division of the inferior laryngeal nerve during the operation is at once followed by complete paralysis of the corresponding cord and aphonia. The old statistics show this to have been a frequent accident in this Billroth had laryngeal paralysis in over 30 per cent of his extirpations. The results obtained by Jackson Pemberton, Berry and other operators have proved that large series of thyroidectomies may be performed without any apparent injury to the recurrents. Improved technique, a fuller knowledge of the anatomical relations, and especially the recognition and avoidance of a danger zone in which the inferior laryngeal nerve crosses the inferior thyroid artery or passes between its branches should prevent the occurrence of vocal cord paralysis after this operation.

Other nerves may be pressed upon by a goitre—namely, the vagus, cervical sympathetic and cervical and brachial plexuses.

From what has been stated it is evident that all cases of goitre should be examined laryngoscopically before undergoing operative treatment. An abductor paralysis may be discovered the responsibility for which the surgeon is then in a position to disclaim. Moreover his knowledge of the presence of the paralysis will lead him to take special care neither to injure further the affected nerve and thus convert an abductor into a recurrent paralysis with aphonia nor to damage the nerve on the opposite side and thus give rise to a double abductor paralysis with dyspnoea.

#### Lymphatic Glands

Lymphatic glands which have become enlarged or sclerosed or have undergone a malignant or tuberculous invasion may readily compress and injure a neighbouring nerve.

The left recurrent laryngeal nerve in its upward course in the thorax and neck is in close relation with the left tracheo-bronchial glands which are seated in the angle between the trachea and left bronchus, and the paratracheal glands which lie in the furrow between the larynx and trachea anteriorly and the oesophagus posteriorly. All these glands receive their lymph from the mucous membrane of the trachea and oesophagus. The stream from the former group flows upwards and that from the latter downwards, and they converge to the supraclavicular region, where they discharge into the venous system directly or through a neighbouring supraclavicular gland.

The right recurrent in winding beneath the subclavian artery passes immediately above a gland which rests on the cervical pleura and apex of the lung posteriorly. Dickey found that in a considerable proportion of the cases of enlarged caseous or calcareous glands in contact with the cervical pleura posteriorly (cervico-pleural glands) associated pulmonary disease was well marked in the underlying lung apex, he is therefore of opinion that a causal connexion between the two conditions is probable, and that either may be primary, but favours the glandular infection as the more reasonable. Paralysis of the right cord always suggests involvement of the right apex, but even if no disease is discoverable in the lung we should keep in view the possibility of neuritis or atrophy of the right recurrent in consequence of a gland pressing upon the nerve close to its origin from the vagus.

Malignant lymphatic glands in the neck and mediastinum not infrequently involve the recurrent laryngeal nerves. We are indebted to our President for tracing a number of these cases to cancer of the mamma, and thus establishing the sequence—cancer of the mamma, secondary glandular enlargement, vocal cord paralysis. If we may judge from the number of cases that have been published since Dr Logan Turner's paper appeared in 1921, this group is not inconsiderable.

The paper referred to was based on 6 cases (5 scirrhus and 1 sarcoma) in all of which the breast and axillary glands had been removed. Leaving out of account the case of sarcoma which affected the right cord, hoarseness set in from two and a half to five years after the operation, and was found to be due to complete recurrent paralysis of the left cord. In two of the five cases, however, the cancer had been in the right breast and was thus contralateral.

In homolateral cases the lymphatic pathway of infection from the cancerous mamma is probably either by way of the axillary or retrosternal glands to the supraclavicular glands, and thence by permeation into the tracheo-bronchial or paratracheal glands which accompany the recurrent. Contralateral vocal cord paralysis is explained by the passing of lymphatic trunks from the inner periphery of the mamma to the axillary and supraclavicular glands of the opposite side. The supraclavicular glands are thus an important junction in the lymphatic circulation of the regions under consideration. A fairly constant member of the group should be sought in the angle between the inner end of the clavicle and the posterior edge of the sterno-mastoid. The axilla should also be examined, and, when the paralysis is on the right side, the apex of the right lung.

#### *Aneurysm of the Arch of the Aorta*

Of all causes of paralysis of the left vocal cord aneurysm of the arch of the aorta is the commonest. As long as the bulging in the convexity of the arch is slight the physical and x-ray examination may give indefinite or no signs of its presence. Increase in the diameter of the vessel at the arch by irritating the recurrent laryngeal nerve may excite neuritis, or by stretching it may cause more or less interruption in its continuity. Similar effects may follow the action upon the nerve of calcareous deposits in the wall of the aorta. The resulting vocal cord paralysis is of the complete recurrent type in the great majority of cases.

#### *Mitral Stenosis with Dilatation of Left Auricle*

The left recurrent nerve may be damaged beneath the arch or in its immediate neighbourhood from other causes than the above mentioned. Of these, perhaps the most discussed is the enlargement of the left auricle following mitral stenosis. In 1897 Ortner reported two cases of recurrent paralysis of the left cord in which at the *post-mortem* examination stenosis of the mitral orifice with great dilatation of the left auricle was found. The auricle passed forwards and upwards, produced some flattening of the left main bronchus, and compressed the left recurrent against the arch. The nerve was thinned and its fibres degenerated at the seat of pressure.

Since the publication of Ortner's paper a considerable number of cases of recurrent laryngeal paralysis attributed

to mitral stenosis have been recorded, in 1924 Vaquez estimated the total at 116. The writers have differed, however, in their explanations of the manner in which the recurrent laryngeal nerve is injured in this condition. Alexander and others accept Ortner's views as to the pathogenesis of the paralysis provided that the left auricle is enormously dilated. Certain observers, on the other hand, maintain that it is not possible for a dilated left auricle to reach the arch and to exert there sufficient pressure on the recurrent nerve to affect it injuriously. Among these was Killian, who stated that it is only necessary to be acquainted with the topography of the heart to be convinced of the impossibility of the relation. Lian and Marceilles likewise believe that the necessary compression is not obtainable unless the wall of the left auricle is rendered more rigid by a lining of organized clot or is surrounded by resisting bands due to chronic mediastinitis. Garland and White support this view, and think that auricular fibrillation, which was present in four of their nine cases, is probably an important additional factor.

Other authorities hold that the distended left auricle transmits pressure through the pulmonary artery, or that this vessel itself when dilated compresses the recurrent (Alexander). Vaquez, and several writers quoted by him, regard the latter mechanism as not unlikely. In Kahler's opinion, based on bronchoscopic investigation, the enlarged left auricle compresses the antero-inferior quadrant of the left main bronchus, which in turn presses the recurrent nerve against the aortic arch. A similar but less marked effect may be caused by the enlarged ventricle pressing the left auricle upwards.

It should further be stated, regarding the part played by the enlarged left auricle in the production of recurrent paralysis, that according to some writers the two conditions are independent, that when found together the association is accidental, and that the recurrent paralysis in these cases is always due to a cause which has no relation to the mitral stenosis—for example, enlarged lymphatic glands and pericarditis. These views gain support from the clinical histories of several cases—one reported and several referred to by Sobernheim and Caro—in which the laryngeal paralysis passed off although the enlargement of the heart persisted.

#### *Ligamentum Arteriosum*

The ligamentum arteriosum passes from the bifurcation of the pulmonary artery to the under surface of the arch of the aorta, and the left recurrent nerve runs immediately to the left of this ligament, or duct—if it retains its prenatal patency. Cases of disease of the heart with laryngeal paralysis are on record in which at the *post-mortem* examination the nerve was found to cross and to be stretched upon the displaced ligament (Kraus) or the duct (Gerhardt, H. v. Schrotter). Such cases must be rare, and can arise only with a greatly dilated right ventricle in a heart lying transversely, which offers resistance at the diaphragm to lateral displacement. The ligament then passes from below outwards and upwards in a plane more nearly horizontal than usual. In v. Schrotter's case the duct was not only patent but widely dilated.

#### *Kyphoscoliosis*

This deformity may be an important factor in the production of recurrent paralysis, either by bringing the arch closer to the distended left auricle, which then presses upon the nerve, or by causing sinking and rotation of the arch so that the nerve is stretched or torn.

#### *Pericarditis*

Recurrent paralysis was first attributed to pericarditis in 1867 by Baumbler. In his case both recurrents were affected on the fourth day of the illness, and about four days later the exudation cleared away and the paralysis passed off. The patient died shortly afterwards, and at the *post-mortem* examination Baumbler concluded that the increase and diminution of the pericardial exudation responded with the development and recession of the recurrent paralysis, also, that the paralyses were due to mechanical pressure. Somewhat similar cases have been reported by

Y. Zinsssen, Biner Iori and others. The paralysis is usually stated to have been caused by pressure of the nerve against the arch by the distended pericardium but it is difficult to see how this could take place. On the other hand pericarditis readily passes into mediastinitis which, as shown below, would account for the paralysis. Certain acute infections which give rise to pericarditis may at the same time cause neuritis.

### Mediastinitis

From what has been stated it is apparent that writers in attempting to account for the laryngeal paralysis in mitral stenosis and pericarditis have assigned the principal etiological role to pressure. In not a few instances this explanation is obviously unsatisfactory and demands too great a stretch of the imagination as to the topographical anatomy of the region in question. This objection has been overcome in a large measure by Adam who has shown that involvement of the recurrent in acute cardiac and pericardial affections is traceable in most cases to inflammation in the mediastinum and is independent of dilatation of the heart.

Paralysis of the left recurrent nerve may therefore be due as has been indicated, to the following cardiac conditions: (1) enlargement of the left auricle exercising pressure on the left recurrent nerve either directly or indirectly through the pulmonary artery or the left bronchus; (2) stretching of the nerve upon the ligamentum arteriosum or ductus arteriosus; (3) kyphoscoliosis; (4) pericarditis; and (5) mediastinitis.

It is evident that the precise cause can be determined only by necropsy. The careful examination of the chest, the consideration of the history and symptoms and of radiographs should assist however, in establishing the connexion. In making a differential diagnosis aneurysm of the aorta enlarged tracheo-bronchial glands mediastinitis and neuritis of toxic origin should be excluded.

It should be noted that the hoarseness may exist before the mitral stenosis has been detected but generally it develops with other symptoms of failure. The hoarseness may be preceded for years (Linn) or only for a night as in one of my cases by a period marked by violent coughing suggesting irritation of the recurrent. At first the hoarseness may be intermittent or the onset may be gradual or sudden. After the apnoea or hoarseness has been present for some time it may become less noticeable owing to the compensatory action of the right cord. The paralysis is always or the complete recurrent type; it is commonly on the left side but may occur on the right. There would appear to be no doubt that the paralysis occasionally passes off when the circulatory conditions improve.

### Oesophagus

Malignant disease of the oesophagus is often complicated by paralysis of one or both vocal cords. The inferior laryngeal nerve may become involved in an extension of the disease from either the wall of the gullet or the adjacent paratracheal lymphatic glands. The left cord due doubtless to its greater length is oftener affected than the right and the paralysis which follows is usually of the complete recurrent type. On the other hand when cancer of the cervical oesophagus gives rise to laryngeal paralysis it is in my experience more commonly of the right cord and of the abductor variety. A possible explanation of the greater susceptibility to cancer of the right side of the gullet in the neck is that the trachea in its downward course is displaced to the right and somewhat twisted so that more or less of the left side of the oesophagus remains uncovered while the right side is not only covered but compressed and irritated by the right edge of the trachea.

The preponderance of abductor paralysis in cancer of the cervical oesophagus may be due to the symptoms being produced either when the disease is in this situation than when it is intrathoracic, and consequently the patients are examined when only the abductor fibres are implicated.

A vocal cord paralysis associated with dysphagia should at once raise the question of an oesophageal tumour. In such case the dysphagia usually precedes the paralysis but not invariably. Oesophageal cancer affords special

opportunities of observing the successive implication of the cords and of their passage from the abductor to the complete recurrent stage.

### Peripheral Toxic Neuritis and Myopathic Paralysis

The reliable information we possess as to this part of our subject is still scanty and of doubtful value.

## II—MECHANICAL IMMOBILIZATION OF THE VOCAL CORDS

BY

HERBERT TILLEY, B.S. LOND. F.P.C.S.

Surgeon Ear, Nose and Throat Department University College Hospital London

It must be some thirty years ago when a man was brought into the London Throat Hospital Great Portland Street, London suffering from a severe degree of laryngeal stridor. We found his cords in complete adduction with slight swelling of the arytenoids. His distress was so urgent that I performed a low tracheotomy at once, and without local or general anaesthesia. The wound having healed, the patient left the hospital wearing a cannula and this he has been obliged to retain ever since. Meanwhile his general health has been excellent.

A year or two after this experience I was consulted by a medical man who had been hoarse for a week, and in addition was suffering from pain in the larynx and in some of the larger joints. I found the left vocal cord motionless in the middle line and its corresponding arytenoid was swollen and oedematous. He went home and to bed was treated for acute rheumatism and made a rapid recovery. Two months later I found his vocal cord had regained its normal mobility and his natural voice had returned.

The possibility of an immobile cord being due to fixation of the corresponding crico-arytenoid joint had not previously come within the compass of my experience. Hitherto I had been taught that such a condition of vocal cord inaction was caused by paralysis due to pressure on the recurrent laryngeal nerve in some part of its course, or less frequently to a lesion in the central nervous system. Hence if it were impossible to establish the presence of an intrathoracic aneurysm or new growth or to obtain evidence of some gross changes in the cerebro-spinal nervous system the cause of the laryngeal symptom remained in doubt the prognosis was considered to be serious and the patient was at least condemned to a more or less inactive life.

In those days the roentgen rays were unknown and physicians were entirely dependent upon their skill in the detection and interpretation of abnormal physical signs and symptoms of disease. They were masters or an art which seems to be in some degree of extinction, because of the present tendency to allow physical and laboratory tests to supplant rather than to supplement keen observation and clinical methods of investigation.

I do not wish to underestimate the value of the hand-arms of medicine, without which our science and art would

indeed be in a very perilous condition. Of such aids radiography is one of the most helpful, in that it will often not only confirm a clinical diagnosis, but give to it details of exactitude otherwise unobtainable. It may be of even greater value still when it discovers the early stages of a lesion before it has had time to produce physical signs capable of detection by inspection, palpation, percussion, or auscultation. A commencing aneurysm of the aortic arch with paralysis of the left recurrent nerve is a case in point.

But many laryngologists must have seen an immobile vocal cord for which every clinical and physical method of examination, often repeated at more or less prolonged intervals, has failed to discover a cause. I wish to emphasize the not infrequent occurrence of such cases because it is obvious that, as between them and cases of true paralysis, the diagnosis with the consequent prognosis places a very serious responsibility upon whoever has the final decision as to the course to be followed by the patient.

In my student days, and for a long time afterwards, a patient with an immobile vocal cord was condemned for many months, or sometimes permanently, to a life of inaction, because such a symptom was considered to be due to a serious paralytic factor, even when this could not be ascertained.

I will give the brief histories of twenty-four patients in whom inflammatory or other factors brought about a temporary or permanent fixation of the crico-arytenoid joint. These cases were included in a series published in the *Journal of Laryngology* (June, 1918), and formed the basis of a communication entitled "Some clinical observations on the significance of paralysis of the left vocal cord." Since then I have seen others which have not been followed up in their subsequent history.

To each of the twenty-four patients I wrote asking for a complimentary visit, or, if that were impossible, for a report as to their condition. I received no reply or only indirect or unsatisfactory information from ten. But one of these was an Austrian, aged 67, who consulted me in 1910, and whom I saw on a golf links in 1915. He had consulted many physicians, laryngologists, and radiographers, but the cause of the immobility of his left vocal cord had never been discovered. He was in perfect health when I last saw him, so it would seem reasonable to assume that he had no serious lesion involving his left recurrent nerve.

Three patients had died, one from aneurysm of the aorta, and one from pneumonia three years after my first examination, but his daughter assured me that in the meantime his voice had completely recovered. The third died from pulmonary tuberculosis, and it is possible that the immobility of his left vocal cord was due to tuberculous infection of the corresponding crico-arytenoid articulation. Four patients remained *in statu quo ante*. The oldest of these was 78, and each patient was seen at least two years after the first examination. Seven patients had completely recovered the mobility of the left vocal cord. (These figures do not quite correspond with those in my original contribution, because then subsequent histories have necessitated one or two of them being moved from one category into another.)

For my present purpose it is only those cases of cord immobility not due to true paralysis which are of interest. Of these there are nine, three remained *in statu quo* and six completely recovered.

Of the three, one is the case of bilateral fixation already mentioned, the man who has worn his cannula for more than fifty years. The second, a man aged 72, was seen in December, 1915, with fixation of the left vocal cord, but was alive and well in April, 1918. The third—a young man aged 27, with adduction of the left cord—was seen in November, 1916, and the condition was unaltered in April, 1918.

Of the seven patients who recovered the use of the left cord, the first was the case already mentioned which proved to be a chronic inflammation of the crico-arytenoid joint. The following details about the other patients are of interest.

2. A married woman, aged 36, consulted me on February 10th, 1908, for loss of her singing voice and inability to speak plainly, the symptoms had lasted a fortnight. The left vocal cord was

motionless in the middle line but there was no swelling of the corresponding crico-arytenoid region. I could detect no physical signs in the chest, and Sir John Broadbent to whom she was referred for examination of the chest, reported that it was normal. Some twelve months later I found that the voice had returned and the action of both cords was quite normal. She died from a cerebral tumour a year or two after she had recovered the use of the left vocal cord.

3. A man, aged 53, consulted me on February 19th, 1910, for loss of voice of two months' duration which dated from a "touch of influenza." No other local or general symptoms were discovered. On March 11th, 1918, both vocal cords were normal in action and appearance. The patient says the voice returned two or three months after his last visit to me.

4. A man, aged 49, consulted me on July 7th 1913 for loss of voice. The left vocal cord was in the position of adduction. There were no physical signs in chest, and no evidence of any central nerve lesion. When re-examined on December 19th 1913 the vocal cords were normal. The patient is still well and in full work as a solicitor.

5. A man, aged 67, consulted me on June 21st, 1915, for loss of voice of three months' duration, it came on after showing on phonation the left vocal cord remained motionless in the middle line. There were no physical signs in the chest and no evidence of any central nerve lesion. On March 5th, 1918, he reported that his throat trouble had disappeared, so that he could talk or sing as well as ever. He douches the throat frequently with cold water and applied a cold water pad at night. In about three months he began to get better, and at the end of four months was quite well. Altogether he was without his voice for about eighteen months.

6. A married woman, aged 29, was seen on February 3rd, 1915, the left vocal cord was motionless in the middle line. Re-examined on April 9th 1915, no change was seen. The patient was a particularly fine and healthy looking woman, but a short time after her second visit she had severe pain in her left heel, and was advised to go to Bath for treatment of her gout by the mineral waters. Her foot recovered, the voice slowly returned, and in July, 1915, I found the left vocal cord had completely recovered its mobility.

7. A man, aged 68, consulted me for loss of voice. His left vocal cord was motionless in the middle line, there was a history of syphilis and patches of leucoplakia on the tongue. The left arytenoid was slightly fuller than the right. After appropriate treatment for six months I examined the larynx again, and found it normal in every respect, and his voice correspondingly improved.

So far as I know, six of these patients are alive and well to-day.

8. In April of this year I saw at the hospital a fine healthy looking man whose right vocal cord was, and still is, immobile and in complete adduction. No physical signs have been detected in the chest, nor has the radiographer found any abnormality therein. He has no difficulty in swallowing, and, but for the alteration in his voice, he declares that he never felt better in his life. It is, of course, too early to make a diagnosis, but the absence of any other lesion is, so far, in favour of a good prognosis.

9. On May 20th I saw a man, aged 84, of whom Dr. de Hallowell Hall reported that about thirty five years previously there had been ankylosis of the right crico-arytenoid joint. I found definite movement on phonation of both the right arytenoid and vocal cord, but there was paresis of the internal tensor causing definite adduction, and hence the huskiness of the voice. It would seem, therefore, that there has been a substantial recovery from the ankylosis noted by Dr. Hall, but there remains a weakness of the tensors of the cord which is probably the result of long continued disuse.

One of the outstanding clinical facts in the first seven cases just reported is that in each of them the left vocal cord was temporarily immobilized. How are we to explain this? Naturally, we shall at once remember the long course of the left recurrent nerve compared with the right, and possibly we may be tempted to speculate as to whether this would render the left nerve more subject to a temporary neuritis than the right. But in my series of seven cases which recovered cord mobility, the first was an acute rheumatic inflammation with oedema of the crico-arytenoid joint. No 6 was probably of gouty origin because it was associated with gout in the foot and recovered concomitantly with the latter. Case 7 was due to tertiary syphilis of the left arytenoid and was cured by appropriate treatment. Obviously, it is not necessary to invoke a neuritis for these cases, in which I was fortunate in seeing the local lesions in their early and more or less acute stages.

It is curious that such obviously local lesions should be so apt to affect the left side of the larynx. To me it is inexplicable as the fact that post-cricoid carcinoma is far commoner in the female sex, or that in prethoracic of the vocal processes the prominence is generally on the left and the depression on the right side.

Testing the mobility of the immobile arytenoid by means of a laryngeal probe has not given me any definite

as a diagnostic measure, but possibly the experience of others may have been more fortunate.

I have said nothing of case of mechanical fixation of a vocal cord due to trauma, or septic infection following injuries by impacted foreign body, nor of the infiltrations produced by tubercle or malignant disease. Instances of these factors are well known and when present are generally easy of detection. In the literature of the subject I can find very little bearing on the type of case to which attention has been drawn.

I venture to hope that my experience may emphasize the fact that an immobile vocal cord is not necessarily due to a grave and often quick fatal lesion. Of course, this contingency must be foremost in our minds when we are confronted with an inactive cord, but if every means of examination should fail to detect such a serious factor it will be our duty to give a guarded diagnosis, a hopeful prognosis and these must be combined with a duly watchful or expectant treatment.

#### DISCUSSION

SIR JAMES DUNDAS GALT (London) referred to the exhaustive exposition of the nervous affections of the larynx by the late Sir Felix Semon, who had drawn attention to the occurrence of crico-arytenoid arthritis as a cause of immobility of the vocal cords. Among the possible sources of error was the fixation of a cord from early post-croupous erysipelas. Bilateral fixation with the cords in adduction was in one case quite inexplicable though possibly gouty, and in another it was due probably to chronic osteo-arthritis. In one case the aphonia and immobility disappeared after bronchocopy being probably caused by a transient inflammatory rigidity of the joints. The speaker recalled two cases of paralysis of the left vocal cord which he had fully reported before the Laryngological Section of the Royal Society of Medicine and which appeared to be due to alcoholism, complete recovery following abstinence.

SIR STCLAIR THOMSON (London) said that Dr Kelly had shown how the subject had been clarified since the British Medical Association last met in Edinburgh twenty-nine years before. Last century was a time when laryngologists still proved each other orthodox by apostolic blows and brocks and their senior in those days Sir Felix Semon used to collect the scraps of those who differed from him in laryngo-neurological righteousness. The subject was in those days, in so much confusion that the writing of the chapter on nervous affections of the larynx in his textbook had given the speaker more trouble than any other. The present generation had only to read the succinct introduction by Dr Brown Kelly to realize how the subject had been made clear. The title of the subject "Immobility of the vocal cords," indicated a final and complete paralysis but the important and interesting cases were those of simply impaired movement. A better title would have been "Defects of mobility, or "Palsy and paralysis." His only personal contribution to the subject had been the publication of observations made on some thousands of cases of a tuberculous sinatorium. During ten years he had found about twelve cases of palsy or paralysis of a cord in cases with pulmonary disease but without laryngeal tuberculosis. Whether this was due to a pleuritis or to a glandular deposit was still unknown. One half of his patients recovered completely, the remaining ones were going about the world with fixed cord, and if they presented themselves without giving their past history the original cause might be overlooked. He suggested that the most likely explanation of the more numerous lesions on the left side was the greater length and exposure of the left recurrent laryngeal nerve. He was inclined to the conclusion that atypical causes of impaired movements were rare and that neurological causes were much the most frequent.

Professor F. R. NACER (Zürich) referred to the involvement of the function of the vocal cord in goitre and stated that in Switzerland generally a distinct vocal palsy would indicate malignant degeneration. Only in very rare cases of sudden enlargement, such as hæmorrhage after

great strain might temporary immobility be observed this disappeared after operation. After greater operations even the best statistics indicated an average of about 8 per cent. of vocal cord affections, but not all would be constant, they were not always due to operative lesion and might be caused by hæmorrhage or the formation of scar tissue. The speaker mentioned a case he had seen of palsy of the vocal cord due to aneurysm of the innominate artery, in which the diagnosis was extremely difficult because there were no further symptoms than compression of the lower part of the trachea.

Dr V. T. LAMBERT (Manchester) gave an analysis of 189 cases of paralysis of the vocal cord (or cords) which he had compiled from the ear and throat department of the Royal Infirmary, Edinburgh during the years 1907 to 1925 (inclusive). These patients had been under the care of Dr A. Logan Turner or Dr J. S. Fraser. Only cases in which the larynx was anatomically normal were included. Cases of immobility of the cord due to tumour or perichondritis were not dealt with. Of the 189 cases, in 181 the paralysis was unilateral and in 8 bilateral.

#### Unilateral Paralysis

Case	Left	Right	Total
Aneurysm of aorta	21	1	22
Operative trauma	5	4	9
Pulmonary tuberculosis	7	6	13
Pleural effusion	1	—	1
Doubtful pulmonary lesions	1	—	1
Influenza (?)	1	—	1
Malignant disease of lung	3	1	4
Wassermann reaction positive (no other cause found)	6	—	6
Syphilis of mediastinum	2	—	2
Tuberculosis of apex with Wassermann reaction positive	1	—	1
Post-diphtheritic	1	—	1
Mitral stenosis	—	1	1
Simple goitre	1	4	5
Toxophthalmic goitre	1	—	1
Malignant goitre	1	3	4
Malignant tumours of neck	3	8	11
Mediastinal neoplasm	15	3	18
Disease of central nervous system	10	5	15
No cause found after investigation	1	5	6
No record of therapy, all of the medical investigation sent to throat department	18	8	26
Totals	135	45	181

Twenty-three of the cases were seen in the adductor stage of these three were later noted as having gone on to complete paralysis (radaric position). In one case of adductor paralysis on the other hand complete recovery was noted at a later visit.

#### Cases of Bilateral Paralysis

Aneurysm of aorta	1
Operative trauma	2
Locomotor ataxia	1
Bulbar paralysis	3
Atrophic lateral sclerosis	1
Total	8

Dr Lambert emphasized the need for better co-operation between the physician, radiologist and laryngologist in determining the causation of motor laryngeal paralysis.

Dr W. S. STARR (Glasgow) said that he had seen a case of right recurrent paralysis due to aneurysm of the innominate artery and three cases of laryngeal paralysis due to invasion of the mediastinal glands in breast cancer. Probably these cases were more frequent than had been thought and it was suggested that a laryngo-optic examination should be made in all cases of cancer of the breast before they were submitted to operation. In some cases of slight paresis of a cord this was present at times and then absent. It would be interesting to have light thrown on the causation of this. While not denying the existence of cases of defective mobility of a cord due to lesions of the crico-arytenoid joint he thought such a diagnosis should be made with reservation. It seemed probable that the cause of these was to be found in the vulnerable position of the left recurrent nerve as it lay in the confined space enclosed by the arch of the aorta and the ductus arteriosus. Short of aneurysmal dilatation demonstrable by clinical examination or x-ray examination it appeared to him that

in many cases there must be such increased pulsation and movement of the vertebra, which by the constant rubbing on the nerve or fretting it caused thickening of the sheath and resulting pressure on the nerve fibres.

Mr C A S RIDOUT (Portsmouth) described two cases. The first was that of an elderly woman with a history of long-continued otorrhoea on the right side which had received intermittent treatment. She came to hospital complaining of aphonia and difficulty in swallowing. On examination it was found that the right vocal cord was immobile. There was no evidence of any lesion in the throat or chest. She came again a month later, when the sixth and seventh cranial nerves were paralysed, she had some difficulty in swallowing and speaking, and complained of severe pain in the right mastoid. A diagnosis was made of malignant disease of the petrous bone on the right side. This was confirmed on opening up the mastoid and at necropsy subsequently. The second patient was a woman with aphonia following "influenza." The right cord was immobile, but no gross lesion was discovered. A few weeks later the right cord recovered but the left remained immobile longer, though it subsequently became normal and the symptoms disappeared. The cause was thought to be neuritis.

Mr M E VLASTO (London) referred to Dr Syme's suggestion that a cause of recurrent nerve paresis might be a fretting action on the nerve due to aortic pulsation, and said that there was a parallel condition in the lower animals. The phenomenon "roaring," which occurred in horses, was known to be due to a left recurrent palsy in an animal usually of the hunter class.

Professor H S BIRKETT (Montreal) stressed the importance of impressing upon students that the larynx should always be examined in the event of even the slightest disturbance of the speaking voice. This statement was illustrated by the examination of a patient whose voice was very slightly affected, the laryngeal mirror showing an abductor paresis of the left vocal cord which was diagnosed as probably a laryngeal manifestation of syphilis. This opinion was corroborated by the subsequent development of all the classical symptoms of the disease. An example of a peripheral lesion involving the nerves at their exit from the jugular foramen was cited, the local manifestations of which were contraction of the pupil, paralysis of one side of the soft palate, hemiparesis of the tongue, and paralysis of one vocal cord—all on the left side. The speaker did not agree that true involvement of the crico-arytenoid joint seldom if ever existed except in that due to malignant disease or tuberculosis, and mentioned a case in which there occurred an involvement of the left crico-arytenoid joint during the course of gonorrhoeal rheumatism with arthritis of the knee- and elbow-joints on the same side. He did not think that most cases of vocal cord paralysis occurring in gonorrhea were apt to be malignant, as he had seen a large number of cases of enlarged thyroid amongst French Canadians, in whom such paralysis without malignancy was fairly common. Paralysis of either one or both cords caused by exposure of the neck to a very cold wind while driving in an open motor car had been seen by him in several cases, the cause being a peripheral neuritis. Recovery ensued in all.

Mr W G HOWARTH (London) thought that the duration of the conditions in each class was of interest. He mentioned a case of right recurrent paralysis due to bulbar palsy which he had followed for twelve years, the patient was still at work, and the lesion had only gradually produced a weakness of the palate, hemiparesis of the tongue, and weakness of the trapezius. As regards the group due to toxic neuritis, he had kept under observation a patient whose recurrent paralysis of the right side began after an acute attack of influenza, the cord did not recover complete mobility for eleven months. He wondered if this was unduly long. He suggested that the temporary paresis mentioned by Dr Syme might be due to early myasthenia gravis. It was important that these cases should be examined by a skilled neurologist, since early cases were very difficult to detect.

Dr DAN MCKENZIE (London) said that the discussion seemed to have dealt chiefly with vocal cord paralysis in which no obvious cause for the symptom could be found, there were undoubtedly many cases of that kind. Middelton and Hunt had stated that most of these proved ultimately to be cases of aortic aneurysm, and certainly vocal cord paralysis nearly always indicated some serious lesion. Nevertheless, there were many which, after lasting for several years, recovered entirely, and there were others in which, although the paralysis continued for a lifetime, no cause was ever found. A puzzling variety was the association of right-sided paralysis with aneurysm of the aortic arch. This was difficult to account for anatomically, but Dr F G Croft had suggested that the vocal cord paralysis might in such cases be due to syphilitic mediastinitis with cervical changes.

Dr ANDREW WYLIE (London) agreed that immobility or impaired mobility was a serious symptom, but it should not have excessive importance attached to it, and only tuberculosis or malignant disease be postulated. Very many patients recovered, and certain toxic cases might escape notice, thus impaired mobility was often a sequel of malarial fever. He had seen cases which were diagnosed as due to enteric fever, and had reported two cases of marked lead poisoning with bilateral immobility which cleared up completely.

Dr T RITCHIE RODGER (Hull) emphasized the necessity of investigating the condition of the adjacent cranial nerves when attempting to explain a laryngeal paralysis. He referred to two cases seen in the same week two months ago.

In a woman, aged 31, the left vocal cord was fixed in the cadaveric position. The left half of the tongue was markedly atrophied, so that when the tongue lay at rest in the floor of the mouth it presented an appearance suggestive of tumescence of the posterior half of the right side. On protrusion, however, the atrophy of the left side was very apparent. The left palate was not very active, but there seemed to be no difference in the two halves. There was well marked wasting of the sternomastoid, deltoid, pectorals, and the supra- and infraspinatus muscles on the left side. There was an almost complete nerve deafness on the left side, but the caloric test yielded normal responses on that side. The voice change and the defective responses on that side the patient had noticed, and these had been present for two years. There were none of the signs of congenital syphilis and Wassermann tests of both the blood and the cerebrospinal fluid were negative, but her father had died of "cerebral tumour" and her mother of "abscesses of the sternum" at the age of 57. The latter condition was particularly suggestive of gummatous disease. Dr Muir who examined the patient thought that syphilitic nuclear disease was the most likely diagnosis. He entertained the idea of bulbar syringomyelia and the bulbar form of progressive muscular atrophy as alternative diagnoses but discarded the former because he could find no dissociated anaesthesia, and the latter because the seventh nerve had escaped altogether and the lesion had remained unilateral for such an extended time.

In the second patient, a woman aged 35, the change of voice had been noticed only six months. The right vocal cord was fixed in the cadaveric position, there was marked wasting of all the muscles of the right shoulder, as in the other case, and there was atrophy of the corresponding half of the tongue. There were no signs of syphilis, and the Wassermann reaction was negative. A ray examination of the chest and neck was negative.

In these cases of involvement of several cranial nerves the lesion might be nuclear, or it might be situated at the point of exit of the nerves from the skull, where cranial nerves had a common or approximate exit. Dr Rodger referred to an article by Dr Veinuro on Verré's syndrome—the common involvement of the spinal accessory, pneumogastric, and glosso-pharyngeal nerves—in which two cases were recorded, one due to inflammatory process in the region of the jugular foramen consequent on a phlebotomy of the jugular bulb, the other due to pressure in the same region from extension of a cylindrical sarcoma of the nasopharynx. In both cases laryngeal paralysis formed part of the picture. The cases described by Dr Rodger differed from the syndrome of Verré in that the hypoglossal nerve was involved, and in the first case the fourth cranial nerve. Although the hypoglossal nerve did not emerge through the jugular foramen until the ninth, tenth, and eleventh nerves it was near enough to be involved in a fairly extensive lesion in that area, and the proximity of the nuclei of the tenth, eleventh and

to fifth nerves, as also of the area acoustica—explaining the deafness—seemed to point to a nuclear lesion as being the more probable explanation.

Mr JOHN T O'MULLIN (London) thought that it was becoming clear that the causes of vocal cord immobility or partial immobility were predominantly neurological. In many cases they could be elucidated, yet there was a large residue for which no explanation could be found. It was obvious that traumatism, disease, aortic aneurysm, and poison (either metallic or pathological) might be concerned. Reasoning by analogy, peripheral neuritis due to exposure to cold was quite conceivable as a cause, as in Bell's palsy of the face. After treating the cause, as it was possible to do in a vast number of cases of vocal cord paralysis, the gravity of the latter symptom could be apportioned, where no such grave cause could be found the prognosis would be favourable.

Dr BROWN KELLY, in his reply, considered that in a case of immobility of the vocal cord when every means had failed to reveal the cause, the possibility should be kept in view of one of the following conditions being present: (1) a sclerosed lymphatic gland which could exercise pressure on the recurrent nerve throughout life and give rise to no other signs; (2) central nervous disease, of which for years the vocal cord paralysis might be the sole manifestation; (3) neuritis due to such causes as alcohol and (4) myopathic disturbances following influenza and other infections. The term "fistling" of the recurrent laryngeal seemed to describe suitably the irritation to which this nerve was exposed when as had been recorded, a temporary increase in blood pressure, presumably accompanied by increased distension of the aorta, gave rise to a transient paralysis which it was recognised by calcareous plates in the convoluted arch. Dr Birkett's description of laryngeal paralysis produced by cold winds was of interest and added another to the category of possible causes.

Mr TILLEY in reply emphasized the early appearance of the local lesion, swelling of the arytenoid as proving the cause to be articular and not neurological in origin. With regard to fretting by the aorta in transient cases he advocated a more thorough examination of the chest by the surgeon and deprecated the too hurried transference of cases to others before any further attempt at investigation was made.

## THE FAILED FORCEPS CASE AND ITS TREATMENT

BY

DOUGLAS MILLER, M.D., F.R.C.S.E.

Lecturer and Senior Assistant in the Department of Midwifery and Diseases of Women, Edinburgh University.

Of the many types of grave obstetric emergency with which in large maternity service has to deal there is none which so taxes the judgement and skill of the attendant or occasions more anxiety in the days which follow delivery than that which comes under the category of the "failed forceps" case. On reviewing a series of five hundred emergency admissions to the Edinburgh Royal Maternity Hospital it was found that in eighty-eight or 17.6 per cent. forceps had been applied and efforts made at extraction without the desired result.

An analysis of these cases shows that the commonest individual cause of failure was disproportion due either to abnormal size of the child or to contracted pelvis the latter being found in varying degrees in about 40 per cent. of cases. The pelvis was for the most part of the generally contracted and flat rachitic types although in seven out of a total of thirty-four cases in this group an outlet deformity was responsible for difficulty. I would especially direct attention to the treacherous nature of this last type of pelvic abnormality—treacherous in that as in five of the seven cases, the measurements of the pelvic inlet may be normal, the head may engage in the brim in a normal

manner, and a good prognosis as regards spontaneous birth may be formed only when the head is arrested at a low level in the pelvis is the abnormality recognized, as a rule the opportunity for Caesarian action has passed, and craniotomy, or at best a difficult forceps delivery is inevitable. Serious outlet contraction of course not commonly encountered in general obstetric practice but the high proportion of cases of this type (seven in thirty-four) in the present series indicates how readily the deformity may go unnoticed.

A posterior position of the occiput was found to be an almost equally common cause of difficulty. In the majority of cases the malposition had not been recognized, and there has commonly been a history of forceps having been applied several times without success. Many of these patients showed severe laceration of the soft parts probably from slipping of the forceps, and in one case rupture of the lower uterine segment had occurred. On admission to hospital the position of the occiput varied in some the head was still in the oblique diameter of the pelvic cavity, in others posterior rotation to the hollow of the sacrum had occurred while in several forward rotation was in progress. In a few cases the head was still riding free above the pelvic brim.

A third group comprised cases in which no abnormality of the pelvis was present, the child was of average size, presentation and position were normal. It is possible that some of these were patients in whom an occipito-posterior position had been present when forceps delivery was first attempted, rotation of the occiput to the front having occurred during the patient's transit to hospital. In a large number of cases in this group, however, no obvious explanation of failure could be found and it was difficult to avoid the conclusion that anxiety to relieve suffering had prompted an attempt to assist delivery before complete dilatation of the cervix and adequate moulding of the head had been allowed to take place. As in many instances of contracted pelvis and the occipito-posterior position above referred to, intervention was unsuccessful largely because it was premature and needlessly entailed not infrequently, serious injury to cervix and vagina. Finally in a small group in which forceps delivery was unsuccessfully attempted there fall to be catalogued two face cases, one of them a menoposerial one brow presentation, and one case of ovarian tumour obstructing labour.

### TREATMENT

Hyperbole might be exhausted in emphasizing the value of prophylaxis. It is however sufficient testimony to the value of antenatal supervision to record that whereas approximately one-third of the cases in this analysis were seen by a doctor for the first time after the commencement of labour, there were on the other hand only three failed forceps cases so far as information is available among more than 6,000 patients who during the period under review, attended the hospital antenatal clinic.

Where moderate forceps traction fails to effect delivery, further treatment will naturally be governed by conditions present in the individual case and in particular by the information which the following lines of investigation afford: (1) What is the nature of the obstruction? (2) Is birth of a living child *per vias naturales* possible? (3) If delivery by the natural passages is contemplated is immediate intervention in the interests of mother or child desirable or not? (4) If delivery of a living child *per vaginam* is impossible do the conditions present warrant or forbid Caesarian section?

### The Nature of the Obstruction

The commoner causes of the obstruction have already been detailed. Careful abdominal examination, accurate measurement of the bony pelvis including the pelvic outlet and vaginal examination preferably under anaesthesia with the whole or half hand will usually yield the information required. Diagnosis of the occipito-posterior position in particular is often difficult especially in those instances in which a large caput succedaneum has obscured the usual landmarks. By the introduction of the hand the position of the head can be determined without doubt, and the existence and degree of pelvic deformity

ascertained. The following test may occasionally be of value in the diagnosis of an occipito-posterior position. If the fore and middle fingers are placed one on either side of the frontal suture the frontal bones may be alternately depressed one on another. As the result of moulding, the occipital and frontal bones are overlapped by the parietals, and one parietal overrides its fellow, so that at the frontal suture alone can this mobility be elicited. The advancing sinciput can thus be readily recognized.

#### *Is Birth of a Living Child by the Natural Passages Possible or Not?*

If the child is dead, or from repeated ineffectual attempts at delivery and obvious signs of foetal distress survival seems improbable, the immediate problem is simplified, perforation being as a rule indicated. Whether or not this should be followed by immediate extraction will depend on the condition of the patient and the degree of dilatation of the soft passages.

If the child is still in reasonably good condition, the possibility or otherwise of vaginal delivery must next be determined. Where dystocia is due to abnormal presentation or position alone, correction of the abnormality is as a rule followed by a rapid and easy termination of labour.

Where, on the other hand, there is disproportion, due either to pelvic contraction or to abnormal size of the child, the following points must be taken into consideration in assessing the possibility of vaginal delivery: (1) Pelvic measurements. (2) The relative sizes of head and pelvis and the degree of engagement as estimated by the Muller-Munio Keri method—a manoeuvre most satisfactorily carried out under anaesthesia with the aid of an assistant. (3) The patient's previous obstetrical history, if she is a multipara. (4) Whether or not the patient has had a real test of labour. It is obvious that where in addition to pelvic deformity labour is complicated by malposition or malpresentation, such as anterior parietal advance in a flat pelvis, the prospects of successful vaginal delivery may be seriously compromised.

#### *Is Immediate Intervention Advisable or Not?*

Where delivery of a living child by the natural passages is considered feasible the important question arises as to whether immediate intervention is desirable or not. In an earlier paragraph it has already been indicated that a premature attempt to effect delivery may not only defeat its own end, but also inflict serious injury on the maternal soft tissues. The ability of Nature to deal successfully with considerable disproportion, if given time, has been repeatedly demonstrated by cases of different types in this series, which were ultimately delivered spontaneously or by an easy low forceps operation, while intervention some hours earlier had completely failed. Moreover, while signs of maternal or foetal distress or arrest from such conditions as face or brow or occipito-posterior position may at any time demand active intervention, the results, both to mother and child, have unquestionably been best in cases in which it has been possible to delay intervention until full dilatation of the passages and the maximum degree of head-moulding have been allowed to occur.

#### *Caesarean Section versus Craniotomy*

Where obstruction is such as to preclude the possibility of successful vaginal delivery there arises the controversial question as to whether, in the presence of probable infection, Caesarean section or craniotomy is the correct line of treatment. Fairquhar Murray has recently drawn attention to the difficulty and danger which craniotomy entails in the presence of serious disproportion, and has strongly urged more frequent resort to Caesarean section in such cases, even where there is undoubted infection and the child is dead. On the other hand, the statistics of Holland and Kerr and of Routh indicate clearly how much more grave is the prognosis where Caesarean section is done in the potentially septic than in the "clean" case, the mortality in the former varying from 10 to 34 per cent. Moreover, Schauta's analysis of 5,000 cases of contracted pelvis shows a maternal mortality of approximately only 4 per cent in 158 cases delivered by craniotomy. The Edinburgh Royal

Maternity Hospital figures over a number of years show a rather lower Caesarean section mortality and a distinctly higher mortality percentage in cases delivered by craniotomy.

While statistical evidence is fallacious, the figures referred to are in accord with the general body of obstetric opinion that where gross infection is suspected as the result of repeated handling, a rising temperature, offensive liquor amni or the development during labour of a purulent discharge, craniotomy entails less risk than Caesarean section.

In no class of case is it less possible to lay down any rule-of-thumb method of treatment. All that I would suggest is that where the child is dead or dying, and disproportion not pronounced, or where major surgical facilities are not readily accessible, craniotomy is the proper procedure, where, on the other hand, the child is alive, the degree of infection slight and disproportion considerable, Caesarean section is warranted. In borderland cases between these two extremes the choice of procedure must depend on the varying conditions present in the individual case and on the personal experience and judgement of the operator.

#### *The Place of Internal Version*

Twenty-five years ago obstetric literature was much occupied with discussions regarding the relative merits and demerits of forceps and version as competitive procedures in labour complicated by contracted pelvis. Partly as the result of ante-natal recognition of disproportion, and partly because of the increased safety of Caesarean section, that type of case in which internal version might be considered the treatment of choice is encountered less frequently than formerly. In Edinburgh, at least, the recognized dangers to the child of a head first labour have resulted in a tendency to restrict version to a small selected group of cases. If such operative procedures as Caesarean section and pubiotomy are inadvisable or not feasible, and the head is riding free above the brim of a moderately contracted flat pelvis, there are three options of treatment—high forceps, internal version, and craniotomy. The high forceps operation almost necessarily entails a faulty and insecure application, large diameters are brought to bear across the pelvic brim, and delivery, if possible at all, can be effected only by the exertion of great force, the usual result being a dead child and a badly traumatized birth canal. Where internal version and craniotomy, and where the above conditions obtain, version may occasionally succeed in saving the child, where the operation is not foiled by severe infection, too great disproportion, or a dangerously thinned out lower uterine segment. I would not put the case for internal version more strongly than that, in the last twenty-six cases of this type in which internal version has been done in the Edinburgh Royal Maternity Hospital all but five of the children were stillborn.

#### *END-RESULTS*

In conclusion, I would refer briefly to the tragic end results of many of the cases in the present series. Seventeen of the eighty-eight patients died—a mortality of 19 per cent, and one which is scarcely exceeded if that associated with any of the major complications of pregnancy or labour. The individual causes of death were sepsis 12, rupture of the uterus 2, post-partum haemorrhage and shock 2, and eclampsia 1. In addition, in thirty-nine (44.3 per cent) the puerperium was morbid according to the British Medical Association standard, many of the patients recovering sufficiently to leave hospital only after exhausting illness, fever. Few patients escaped without more or less laceration of cervix, vagina, or pelvic floor. Slightly more than half the vaginal tissues with fistula formation occurred in the cases. Further, it will be appreciated that primipara was seldom feasible or successful. Many patients were perforce discharged only to face many weeks or months of further ill health, and in a few the future was permanently invalidism. Including stillbirths and neonatal deaths, forty-six of the infants were lost—a mortality of 52 per cent.

## CONCLUSIONS

The conclusions suggested by this clinical analysis may be summarized as follows:

1 The overwhelming evidence in favour of careful ante-natal examination, particularly in primigravidae and in multiparous women with an unsatisfactory previous obstetric history.

2 The importance of careful routine measurement of the pelvic outlet, which may be contracted in spite of a normal superior strait, and is thus a deformity specially liable to be overlooked.

3 The grave danger entailed by non-observance of elementary rules with regard to the application of forceps through an incompletely dilated cervix or in the presence of marked disparity in the relative sizes of head and pelvis.

4 The necessity when moderate forceps traction fails of recognizing the nature and degree of obstruction and of determining whether vaginal delivery of a living child is possible or not.

5 The remarkable capacity on the part of Nature, if given time, to overcome considerable disproportion by moulding of the head and the realization that the condition of mother or child rather than the actual number of hours passed in labour, should constitute the indication for assisting delivery.

## DISCUSSION

Dr BETHEL SOLOMONS (Dublin) did not quite understand what treatment had been given to those patients who had died. He personally had a very decided preference for pubiotomy or lower segment Caesarean section to craniotomy on a living child.

Mr R H PARVORE (Rugby) referred to his experience in cases of pubiotomy.

Professor FLETCHER SHAW (Manchester) regretted that this very important paper had been crowded into the end of a long morning's work. It was most unfortunate that this could not be given to his discussion and he urged that this subject should be fully dealt with at the meeting next year at Cardiff.

Professor McILROY supported Professor Shaw's proposal and the PRESIDENT (Dr Hug Ferguson) agreed that the suggestion should be made in the right quarter.

## MEDICAL, SURGICAL, OBSTETRICAL

## FORMALIN POISONING RECOVERY

As poisoning by formalin is a rare accident according to the textbooks of toxicology, the following details of a case of poisoning may be of general interest.

On September 5th I was called to see a boy aged 7 who was showing symptoms of poisoning after drinking some disinfectant. Arriving at the house about fifteen minutes after the poison had been swallowed I found that the patient had entered a room which was being disinfected by a workman by orders of the local sanitary authority, seeing a bottle on the floor containing a liquid which he took to be lemonade he drank the remainder of the contents of the bottle assuming to possibly halt an ounce of the liquid.

I found the boy somewhat collapsed though quite sensible he complained of a burning pain in his throat and epigastrium. His pulse was rapid and weak he had vomited once bringing up a quantity of clear greenish fluid and he was gasping for breath. The nature of the disinfectant was unknown to the workman who had gone away to inquire as to its composition. I smelt the vomited matter and at once detected that pungent odor so familiar to those who have frequented a dissecting room. I decided that the poison must be formalin. This conclusion was subsequently confirmed by the workman on his return the disinfectant being commercial formalin a 40 per cent solution of formaldehyde in water.

The treatment I adopted was washing out the patient's stomach through the pyloric tube, I then introduced a quantity of very dilute solution of ammonium which was left in the stomach. The latter procedure was an attempt to produce the well known reaction by which ammonia and formaldehyde unite to produce the condensation product hexamethylenetetramine more familiarly known as urotropine or hexamine a harmless compound. I also caused the patient to be put to bed with hot bottles and enemas in traction for the administration of demulcents. The child

now appeared fairly comfortable. On the following day the patient was in his usual health except that he complained of slight pain in the throat on swallowing he has since made an uneventful recovery.

From a study of the literature available, it appears that one ounce of commercial formalin has proved fatal for an adult. From what I was told the quantity swallowed by the boy would probably have been a half dose for a child of the patient's age.

## A CASE OF SIMPLE CLEFT STERNUM

Cleft sternum is a sufficiently rare condition to justify a record of the following example.

The subject was a healthy girl aged 11 with an uneventful medical history. Though the deformity was noticed at birth particular attention was not drawn to it until the girl was examined at a school clinic and doubt was then expressed as to whether she was fit to play games owing to the risk of a blow on the chest.

In the anterior wall of the thorax there is a marked depression due to complete absence of the pre-sternum. The ends of the clavicles are separated by a gap of about two inches during expiration which increases to two and a half inches on inspiration. The cleft extends down as far as the fifth costal cartilage the ends of the upper four costal cartilages on each side being connected by a fibrous or cartilaginous strip. The cleft narrows as it approaches the fifth costal cartilage where the two halves of the metasternum become joined by a band of strong fibrous tissue from the fifth to the seventh costal cartilage. A xiphisternum could not be felt.

There is a slightly asymmetrical appearance of the chest but measurement does not confirm this, both sides being equal and no kyphosis or scoliosis being present. In the depression formed by the absence of the sternum the pulsation of the aorta is very marked. The heart is normal in size and position and no cardiac murmurs are audible.

During coughing or forcible expiration the anterior edges of each lung herniate through the cleft, this produces an alarming swelling on the front of the chest. This condition gives rise to no discomfort to the child except if pressure is applied such as would be present if the sternum were complete.

Dr W Greig has collected from the literature twenty cases of simple cleft sternum. Six of these cases had concomitant anomalies. In the one here described no other abnormalities could be detected apart from an unusual amount of extension at the elbow.

I am indebted to Mr F Cyril Dobie senior honorary surgeon to the Chester Royal Infirmary for permission to publish this case.

Late Senior House Surgeon Chester Royal Infirmary

## ACUTE PULMONARY OEDEMA RECOVERY

During the last few months several cases of acute pulmonary oedema have been reported and therefore the following details of an instance of recovery following an attack seem worthy of record.

A man aged 60 was seen at the end of June 1927 on account of an attack of follicular tonsillitis which responded rapidly to treatment. He did not feel ill in himself and remained at work. During the night of June 12th I was called to see him. He was sitting in a chair very anxious, breathing rapidly and with great difficulty and expectorating large quantities of blood-stained sputum. His chest was full of moist rales and the heart sound was very weak. His pulse was 140 and thready. The attack had come on about a quarter of an hour previously following sudden diarrhoea. He was given 100 grains of atropine sulphate and 180 grains of strychnine hypodermically at once and propped up in bed with his water bottles to his feet. He improved and was then given hypodermic injections of 1/12 grain of heroin and 1/100 grain of atropine sulphate. In about half an hour his breathing became more comfortable and the frothy expectoration almost ceased. He slept at intervals for the next twelve hours. He was kept under morphine for forty-eight hours and by that time his chest was quite clear of rales and his pulse rate had fallen to 80.

The attack in this case was probably brought on by distension of the stomach following a heavy meal just before bedtime. The patient's cardio-vascular system and urine showed nothing abnormal. He was quite fit three weeks after the attack and has kept well ever since.

### THE HEALTH OF THE NATION

THE strategic front in the campaign for the common health is held in the centre, as is necessary and proper, by the medical profession. It has many brigades and numerous methods of warfare. At the moment the most needed and effective of these methods is the spreading of knowledge among the public on health matters, and a new weapon for this offensive will be found in a book entitled *The Health of the Nation*,<sup>1</sup> just published, by Dr F E FREMANTLE, M.P. These military metaphors are not inappropriate in the case of an author who has seen so much service both in actual warfare and in the party strife of the House of Commons and the constituencies. These experiences, together with those of a county medical officer of health, have enabled Dr Fremantle to take a wide view of the position from some unaccustomed angles, and the result is a piece of work well worth doing, admirably done, and likely to be of real value to several classes of readers.

Publications, whether books or articles, on health matters intended for non-medical readers are of various kinds. Many of them have a tendency to be mere chatter, mostly platitudinous or futile, and the chatterer, even if a member of the medical profession, often has no particular qualifications for speaking with any authority on the matters with which he deals. Such publications are, on the whole, a hindrance rather than a help in any campaign. Then there are a number of little books on personal hygiene intended mainly for use in the junior classes of schools. These, however good in themselves, are largely wasted efforts, for such instruction is much more effective when given orally and practically by a teacher than when gathered from any book or pamphlet, however simple and elementary. There are also admirable textbooks on domestic and public hygiene for use by senior pupils and in technical classes. These are founded on the basis of physics and chemistry, and are, in fact, textbooks of elementary applied science, leading up to those larger volumes which are necessary for all who intend to make sanitary science their life work. Dr Fremantle's book is none of these things. He approaches his subject not as a branch of science, but as a branch of civics. It is, as he tells us in an introductory note, an attempt to "bring together in right proportion the main facts and factors in the health of the people and the general system of law, authority, and administration affecting each issue", or as Mr NEVILLE CHAMBERLAIN, the Minister of Health, describes it in his foreword, "a useful and comprehensive review of the organization and purpose of our public health service".

The book begins with a very brief history of public health organization in this country. There follow chapters dealing with statistics and problems of population and with the records of births, sickness, and death. Dr Fremantle then considers what he calls the "economics of health" in the form of a profit and loss account, showing on the debtor side the loss due to absence or lessened efficiency owing to ill-health, the cost of care and treatment, the indirect loss from epidemics, and the maintenance cost of health services, and on the creditor side the profit from lives saved or prolonged. We may well doubt, with Mr Neville Chamberlain, whether such financial calculations "provide a true value for things which in themselves are incapable of measurement," but there is a certain order preserved to which monetary considerations make the more frequent appeal, and there is no reason why some attempt even where it is made to impress such minds by estimates on dead. On those which Dr Fremantle gives. The author Keir and of him account of the constitution, powers, and is the prognosis of health authorities and officers, and potentially septid these operate in regard to pure food and in the former va mill, light and air, questions connected Schauta's analysis.

<sup>1</sup> *Nation*. By F E Fremantle M.P. M.B., M.Ch.  
With a foreword by the Rt Hon Neville  
Chamberlain, Minister of Health. London: P. Allan and Co., Ltd.  
209 8s 6d net.)

with maternity and infant welfare, school sanitation and medical services, the Poor Law, hospitals of different types, old age pensions and the various social insurances, including national health insurance. He then deals with the attack on certain special diseases, particularly infectious fever, tuberculosis, cancer, venereal disease, and the effect of alcohol and the regulation of its sale. Some administrative and legal points connected with mental disorder and deficiency, and with industrial disease and venereal and the employment of various classes of persons, are touched upon, and there follows a description of the regulation of the medical, dental, nursing, and veterinary professions, and of the work and training of pharmacists, sanitary inspectors, and health visitors. The special conditions which prevail in Scotland under all these headings are set out, and a concluding chapter briefly deals with the Navy, Army, and Air Force Services, with the Indian and Colonial Service, with the work of the Ministry of Pensions as regards health, and with the health organization of the League of Nations.

The comprehensive character of Dr Fremantle's survey is thus evident, yet it is made within moderate compass, perhaps too small. The method is to give the bare fact, frequently with statistics wherever this has seemed desirable. The various problems that present themselves are never really discussed, and even expressions of opinion are not very frequent. This leads to conciseness, but it is of interest. The method was no doubt deliberately adopted in view of the main purpose for which the book was intended. The book is, indeed, so good for its purpose and so certain to require revision for future editions that it may be worth while to point out a few minor blemishes and to make a suggestion or two for the author's consideration. The historical chapter is really too meagre. It should not be long, but the historical method of approach to any branch of civics is usually most effective and illuminating. One small illustration may be given. Edwin Chadwick is mentioned. The dates of his birth and death are given, and the fact that he was a barrister. And this we are told merely that he was the founder of our system of public health, and that Disraeli considered him "a monster in human shape." This must be tantamount to those who know no more of Chadwick, and his importance in the scheme of things clearly justifies Dr Fremantle's readers in asking for more than this. Very curious, again, considering the author's own close parliamentary association with the matter, the main paragraphs on the registration of deaths appear to describe the old and not the recently enacted methods, and more might have been said about stillbirths than the mere statement that their registration is now required. The description of "national benefits"—especially those known as National Health Insurance Acts requires expansion, for the Act is becoming of great importance. Again, merely as an example of the kind of thing which might be done here and there in various chapters, if to such a paragraph as that dealing with the employment of children on page 143 there were added the general nature of the by-laws made by the best local authorities, thus indicating some of the dangers from which children were being protected, interest would certainly be increased.

Lastly, one point of a different kind may be noted. Every now and then when health proposals or facts are mentioned there is reference to a commendatory tendency to one political party, whereas in similar circumstances other parties are ignored or are very occasionally alluded to in a depreciatory tone. This does not loom very large in the book, and if it is to be regarded as a superior and excellent piece of political propaganda, and is so recognized, no harm is done. These things are, however, not so useful to a textbook, and if, as we hope, this volume becomes a largely used textbook or handy reference book for students of civics, for members of Parliament, of town and county councils, of committees and associations interested in health and social welfare, and also perhaps for medical students and qualified practitioners, very few alterations will do all that is needed. In any case the book can be strongly recommended to all these persons.

## A TEXTBOOK OF UROLOGY

Dr O S LOWLER and Dr T J KIRWIN are well known by genito-urinary surgeons on this side of the Atlantic for their pioneer work in regional anesthesia and their numerous important contributions to urological literature. They have now crystallized their laboratory and hospital experiences of the last eighteen years in *A Text-Book of Urology*.<sup>1</sup> In writing it their chief difficulty has been to compress what they have to say within the covers of a single volume so as to produce a work of dimensions suitable to the needs of students and practitioners. In order to economize space the historical survey of urology has been cut down to a single chapter and, instead of quoting the work and opinions of other authorities, a bibliography has been attached to the end of each section. The arrangement is that which is most usually employed. We have a preliminary chapter on history-taking, physical examination, cystoscopy and radiography, followed by sections dealing with the various diseases that may affect the genito-urinary organs grouped according to their anatomical relation. In a chapter on diseases of the testicles, epididymis, vas deferens, and seminal vesicles a considerable amount of space is devoted to the subject of operations for relief of sterility. Martin's operation is described with the various modifications of his technique introduced by other surgeons. It is a pity, however, that no indication is given as to the prospects of success offered by these procedures, for there is little to be gained by studying details of technique if attempts to cure sterility by surgical methods are foredoomed to failure. In England the operation or epididymo-vasostomy has to all intents and purposes been abandoned, as no surgeon has yet been able to publish a successful instance of its employment.

Dr O S Lowler's researches on the embryology of the male urethra and the development of the prostate are widely known, and the chapters on the male urethra and the prostate are therefore of particular interest. The authors, although they are in the main partisans of perineal prostatectomy, are of the opinion that the urological surgeon should be prepared to adapt himself to the individual need of the patient and to carry out either perineal or suprapubic prostatectomy. Their preference for the perineal route is based on the fact that it causes less shock. In combating this shock, should it occur, they recommend the use of a 5 gm glucose solution as suggested by the late Sir William Baylis in his memorandum on the treatment of shock following war wounds.

The bladder and its associated pathological conditions are dealt with in chapter xi. The description of the anatomy and embryology of the bladder is excellent and so in the main is the account of its surgery. The criticism may, however, be made that the account of per-urethral methods of treating bladder growths is not so complete as it might be. Recent years have been productive of so many advances in the way of new forms of operating cystoscopes and new methods of applying diathermy that more space might well have been given to this important subject.

The illustrations have been well selected and have been derived from the researches and from the patients of the authors. Their work appears to have been done mainly at the Bellevue Hospital and in the Department of Urology at the New York Hospital. The volume should be a useful addition to the library of any genito-urinary surgeon or any general surgeon undertaking genito-urinary work.

## PHYSICO-CHEMICAL EQUILIBRIA IN THE ANIMAL BODY

We share with the author the difficulty of finding a brief title which will adequately convey the scope of the small but crowded volume *Factors Affecting the Distribution of Electrolytes, Water, and Gases in the Animal Body*.<sup>2</sup> Dr

Dr D D VAN SLIKE. It forms the latest addition to the stimulating series of Monographs on Experimental Biology. The author's subject might be described as the regulation of the acid base neutrality of the organism, and such it is yet it is so very much more. The neutrality of the body is not to be measured in equivalent of acids and bases. It involves the whole intricate balance of electrolytes and colloids in the serum, blood cells, and tissues. It casts the versatile haemoglobin in a dominant role, it takes account of permeability, and it demands a just appreciation of the activities of the respiratory apparatus and the kidney. "One thing leads to another" and a change in the composition of the alveolar air or in the acid base equilibrium of the blood reverberates through the whole physical structure of the animal, so that every physiological function seems to give back some echo of the disturbance. Here we find physical action and vital reaction reduced to quantitative definition in the language of physical chemistry with a compelling precision. The author writes:

The resultant picture is not complete and probably never can be. Nevertheless, so many once inexplicable processes have been found to occur in accordance with the recognized laws of physics and chemistry and such an extent of correlation amongst processes in the body has been observed that one may hope by a casting of accounts at the present moment to add more order than confusion to physiological thought.

The claim is modest. No geographers of the dark places of physiology have given us a more complete map of their territory than the nomograms which Professor L. Henderson has constructed from the data arduously collected in the laboratories of Dr Van Slike and others. They go far towards reducing to two dimensions the complex traffic in gases, water, and electrolytes which is the constant burden of the living organism.

The story told by the author is fascinating, though a little too austere and concise. Students of biology not deeply versed in the precepts of physical chemistry would enjoy his book the more had he mitigated the severity of his argument with a greater expansiveness. One or two of the diagrams have been reproduced in a fashion which does credit neither to the investigations which they exemplify nor to the series of monographs to which this volume belongs.

## NERVES FOR THE LAYMAN

Professor FRANK HARRIS is the general editor of a series of excellent and popular health books, some of which have been reviewed in our columns. He has now written a book himself which is the twelfth of the series. He has attempted what is, we believe, one of the most difficult pieces of popular health instruction for he has written on *Nerves, Voster System of the Body*,<sup>3</sup> is the title of his book, and in it he points out that whereas the layman has some knowledge of his muscles, for he can feel them and of his skeleton for like reason, and of his digestion (and sometimes too much of that) he knows very little of his brain and of his nerves, for these are hidden and impenetrable and therefore mysterious. So the author has set himself to tell the layman what this great system is and how it is the true master of his body from the physiological point of view, and often from the psychological. He first gives a general sketch of the anatomy of the brain, spinal marrow, and the nerves then proceeds to afford a general idea of how the nervous system works, how impressions enter through its parts, how they react in pain, and what pain is and to what it is due. His description of the nerve centre is particularly good as is his exposition of reflex actions which form so great a part of our activities, but there is a slip on page 107 where the papillary light reflex is said to be "the effect of light on the iris." Finally he discusses the physical bases of consciousness, and explains what are the effects of fatigue, what is the nature of sleep of dreams and of those waking dreams of hypnotism.

The discussion of recent psychological theories of the unconscious mind and its effects will be really informing to the layman, somewhat—perhaps completely—banned.

<sup>1</sup> *A Text-Book of Urology*. By Oswald Swanner Lowler, A.B. M.D. F.A.C.S. and Thomas Joseph Kirwin, Ph.D. B.S. M.A. M.D. Philadelphia and London: Lea and Febiger, 1926. (6 x 9 pp. xviii + 679. 25 figures. 15 plates. 10 do. line.)

<sup>2</sup> *Factors Affecting the Distribution of Electrolytes, Water, and Gases in the Animal Body*. By Donald D. Van Slike, Ph.D. Sc.D. Monograph on Experimental Biology. London: J. B. Lippincott, 1927. (10 x 6 in. pp. vi + 62. 15 figures. 10 do. line.)

<sup>3</sup> *Nerves, Voster System of the Body*. By David Frank Harris, M.D. D.S. Birm. B.Sc. Lond. The Modern Health Book. London: Faber and Gwyer (The Scientific Press), 1927. (Fcap. 8vo. pp. 222. 14 figures. 32 do. line.)

with the gushings of the novel writer. The last two chapters are devoted to considerations of mental hygiene, to explaining what nervousness, irritability, and melancholia are, and the best way of maintaining neural health. He is a firm believer in the dominance of the first seven years of life, when the health of the nervous system is made or marred, for as the child is directed in these early years so will he incline for the rest of his life.

Professor Fiasci-Harris has undertaken a difficult task, but he has done it uncommonly well, and produced a book that is readable, informative, and balanced.

### MILITANT MEDICINE

THE title *Aesculapius Armaque*, which Major RITCHIE of the Royal Army Medical Corps has chosen for his series of articles on military medical subjects, provides the "arma virumque" of our school-days, but is neither so euphonious nor so robust as the Virgilian original. Be that as it may, everyone who is interested in the author's criticisms on war and the medical service, which have already appeared in the *Journal of the Royal Army Medical Corps*, will be glad to have them published in one handy volume, for the articles are full of excellent ideas, afford much food for thought, and are written in an incisive and distinctive style.

There are a dozen articles in all. The first two are the longest and are, perhaps, the most interesting. *Mars et Hygea*, the heading of the first—we are thankful it was not *Hygea Marsque*—contains a series of paragraphs on the relationship of preventive medicine to the conduct of war. The author foreshadows a time when men with medical qualifications will study war in all its branches at military schools, until the greater part of the duties and responsibilities of the administrative services will rest in the hands of the medical officer. The historian of the Trojan war described the medical officer as *αἰνὴν πολλὴν ἀνδρείου ἔχων*. Thus do Homer and Major Ritchie think alike. "Hygiene," according to the author of *Aesculapius Armaque*, "may become Q." We cannot follow him so far. He refers to hygiene as having been misused in penury, and implies that good sanitation in the field is largely a matter of cupidity, its appliances being constructed from the leavings of other services, such as empty ration boxes, oil drums, and petrol tins. This is all very true, field sanitation being essentially a matter of improvisation. But it scarcely amounts to the elaborate and complicated functions of a quartermaster-general's branch. Other paragraphs of this chapter wander in an easy saunter through wide fields. They touch on evolution of armies, fashions in fighting "as variable as women's clothes," types of transport, the Geneva Convention which may "pete out," and skin affections, culling their flowers of diction where they may. Prophetic and somewhat gloomy visions of future warfare end in a well deserved eulogy of the work of the army medical service before the war. "The foundations of its fame were carefully laid during the years of peace, its preparations were remarkably complete, it saw big and thought big, and it was perhaps the keenest branch of a keen pre-war army." "*Sententiae vagae*," the heading of the next article, would have been more appropriate for the first, and scarcely indicates its character, for it is concerned mainly with army medical organization before during and after the war, and the various modifications induced by circumstances or suggested by a hypothetical future.

The remaining articles refer to similar subjects, such as the efficiency value of a wider outlook for the medical and other services of the army, the pros and cons of chemical warfare, a vigorous policy in hygiene, bacteriology in the next war, and certain domestic matters affecting the Royal Army Medical Corps. They are all well worth reading if only for the enjoyment of Major Ritchie's arresting style of writing. It is not too much to say that *Aesculapius Armaque* shines as a new constellation in the firmament of army medical literature, and brightens a type of writing that has seldom emitted sparks from its somewhat massive solidity.

*Aesculapius Armaque*. By Major M. B. H. Ritchie, DSO, R.A.M.C. London: J. Bale, Sons and Danielson, Ltd. 1927. (Demy 8vo pp. 112 5s. net.)

### NOTES ON BOOKS

A VALUABLE service has been done by Dr R. H. A. Plimmer in the production of his textbook on biochemistry. Biochemistry has been generally somewhat hampered through a lack of books devoted expressly to the subject. The necessary literature for a vigorous pursuit of the study was too much scattered for easy access. Authors of textbooks were formerly too reluctant to specialize. The older school adhered to the view that chemistry could not be properly understood if the study were confined to a single branch of it. This view was proper when the whole range of chemistry was shorter, and it is still true that the foundation of chemistry is the same for all its branches. But as chemistry extended its boundaries its branches became more disconnected, and it is now almost impossible to deal with any one of them except as a unique subject. In this development there is, it is evident, a danger that the fundamental principles of chemistry may also be made sectional for different groups of students. Dr Plimmer has deliberately avoided this danger, and has emphasized his action in the title he has chosen, which describes the volume as a textbook of organic chemistry directed to its biological aspects. It conjoints practical and theoretical treatment in a well connected arrangement, thus facilitating as well as encouraging careful and thorough work. The present form of the book is a development from earlier editions, revised in accord with the dictates of experience.

Yet another small manual comes from the indefatigable pen of Dame MARY SCHARLIEB. It is written in conversational style, but with the clarity which characterizes all her books. It is entitled *The Psychology of Childhood*, but the preface states that it is not intended to be a treatise on the psychology of children, but as a popular guide for parents in their difficult and important task of preparing the children of the present day to be the parents of the future. The early pages are devoted to a consideration of the development of the senses of the infant, the links between mind and spirit, and the child's religion. Chapter IV deals with parental duties. After quoting the present birth rate the author says: "To whatever cause we attribute this enormous falling off of citizens to our shores, and whether we consider this condition an asset or a detriment it is surely evident that the smaller number of children on whom to be more carefully guarded and more wisely instructed if we are to have an adequate supply of healthy, well trained and spiritually satisfactory citizens." The remainder of the book, with the exception of the final chapter, is given to the consideration of the various groups of abnormal children. Dr Scharlieb explains the accepted definitions of "idiot," "imbecile," "Mongolian," etc., and quotes figures showing the percentage proportion of each to the population. This is a very useful part of the book, and should clear away much misapprehension on the subject. The last chapter deals with suggestion, discipline, and punishment, and should be helpful to all who have any dealings with children.

Dr T. M. DISHINGTON has written a little book which seems to be his confession of faith in the system of medicine to which he adheres. It is cast in the form of a novel—*The Patient's Dilemma*. The novel is slight, the most of it a dialogue between a doctor perplexed with the problems of sickness and one who is filled with a sublime confidence in the powers of the simulum. Assuming that the expert is put in the mouth of one of his characters are those who author holds, Dr Dishington is a whole hogger for the cause of homoeopathy. For the most part the argument is what we have heard before, the revelation of the simulum, and the defence of the infinitesimally small dose, whose power is held to be proved since it is alleged that in such diluted the drug assumes a colloid form and therefore is the assimilable and potent. Sometimes his argument runs away with him. The treatment of insanity by this system is well discussed, and on one page we read, "A healthy boy receives a head injury becomes an uncontrolled fiend. The surgeon, by merely restoring the internal plate of the skull to its proper alignment may cause a complete disappearance of every morbid mental process." On the opposite page we read, "A person with a frail physique and a tubercular lung may have a clear brain, and the natural sweet disposition may have full expression, but if the lung state has been healed by local means, the disease force, not neutralized, cured, may expend itself on the brain and insanity is the ultimate end of the patient." This is a strange doctrine.

\* *Practical Organic and Biochemistry*. By R. H. A. Plimmer. 1926. (Royal 8vo pp. 74 + 563, 67 figures, 1 plate. 21s. net.)

The cure of a local lesion of the brain brings sanity, but the cure of a local lesion of the lung brings insanity! Considering the known frequency of healed tuberculous lesions of the lung in the population generally most of us should be insane. The humorist says we are! It is not clear for what class of reader this little book is written, the layman would scarcely understand it though he might be mystified, for the medical reader (and since the dialogue is between medical men it would appear to be for them) it is somewhat thin.

### IMPERIAL SOCIAL HYGIENE CONGRESS

An Imperial Social Hygiene Congress, organized by the British Social Hygiene Council, was held in London, under the presidency of the Right Hon. Major General J. E. B. SEELY, during the first week of October. It was attended by delegates from Government departments, home and overseas, certain international bodies, such as the League of Nations Health Organization, six British and three Indian universities, about forty local authorities in Great Britain, and a large number of medical and educational societies and societies interested in social welfare. The British Medical Association was represented by Dr. H. G. DAIN, Dr. C. E. S. FLEMING and Mr. Bishop HARMAN. The Congress did its work in six sections which had for their subjects the medical, the educational, and the administrative aspects of social hygiene, and the problem of venereal disease in India, in the colonies, protectorates, and mandated territories, and among seamen.

The Congress opened with a banquet at which Mr. Neville Chamberlain, Minister of Health, was the principal guest. Mr. CHAMBERLAIN, in proposing the toast of "Health and Empire," referred to two health projects which, centering in London, had much imperial significance. One of these was the London School of Hygiene and Tropical Medicine, which, when housed in its new building in Gower Street, would make London more than ever a world centre for the study and control of the scourges of the tropics. The other was the project, now at the point of realization for a post-graduate school in London thanks to an arrangement between a committee over which he himself had presided and the authorities of the West London Hospital. Such a school would afford far-reaching opportunities for medical men from all parts of the Empire. The toast of "Delegates and guests" was in the hand of Mr. E. B. TURNER who referred with great gratification to the growth and the widening scope of what was originally the National Council for Combating Venereal Diseases. Among those who responded were Professor JADASSOHN, president of the corresponding German organization and Sir FAZL-I-HUSSAIN, a member of the Indian delegation to the Assembly of the League of Nations, who emphasized the high qualifications of the men in control of public health in India.

#### *The Modern Treatment of Syphilis*

The medical session, under the presidency of Mr. DAVID LEES, produced two outstanding contributions. The first was by Colonel L. W. HARRISON, who spoke on the modern treatment of syphilis and its results. He emphasized the importance of starting treatment before the serum reactions became positive. The minimum amount of treatment for a sero-negative primary case, in his experience at St. Thomas's, was twenty injections, totalling 10 to 12 grams of "914," with mercury or with bismuth and for sero-positive primary and early secondary cases, quite 50 per cent more. The method of administering mercury or bismuth simultaneously with arsenobenzol had advantages over that of following a course of one by a course of the other, especially from the point of view of preventing neuro-recurrences. The coincidence of negative reactions in serum and positive in cerebro-spinal fluid was so uncommon, and two inconveniences attending lumbar puncture were so great that routine examination of the fluid might safely be omitted in cases which run a straightforward and satisfactory course from the serological point of view.

The other paper was by Professor F. J. BROWN, director of the obstetric unit, University College Hospital, who spoke on the management of cases of venereal disease in ante-natal and post-natal clinics. He laid down a series of principles which he regarded as the minimum necessary

for the proper diagnosis and treatment of venereal disease in pregnancy, and advocated compulsory notification of pregnancy at an early period, say the third or fourth month, only in that way could all cases of syphilis in pregnancy be discovered at a stage when effective treatment might be carried out.

#### *Administrative Aspects of Social Hygiene*

The session dealing with the administrative aspects of social hygiene was presided over by Dr. T. F. DEWAR, medical officer of the Scottish Board of Health, who said that in Scotland the incidence of venereal diseases was regarded as being still far too high, although there were indications that syphilis at least was less common and formidable than it was ten years ago. The need for further legal powers was being considered in Scotland cautiously but earnestly. Dr. J. R. KAYE, medical officer of health for the West Riding, referred to the special administrative difficulties with regard to gonorrhoea, and especially in that large class of married women suffering from this disease with whom the authorities found it exceptionally difficult to get into touch. One solution might be to have clinics open for admission at any time of the day, and to provide special facilities at child welfare centres, so that the women could attend with due regard to their household duties and without fear of neighbours' comments. There were other persons who were totally indifferent to treatment, for them probably the only incentive might be the visualization of museum specimens showing the results of venereal diseases, as in the Hunterian collection. The following up system in the past had not been adequate, for 20 per cent or more had relinquished treatment prematurely. Some means such as notification, and, if necessary, threatened publicity, was indicated in his opinion, particularly when the lapse might mean infection for others.

Dr. T. FERGUSON, venereal diseases officer at Darlington, read a paper on congenital syphilis as a problem in public health administration, and deplored the delay which was common before the infected child received treatment. For the administrator, he said the two salient facts concerning syphilis in the pregnant woman were that active specific treatment of the mother during pregnancy could almost eliminate congenital syphilis and that the earlier in pregnancy the treatment was instituted the greater was the certainty of securing a healthy child. Every ante-natal examination should be made with the possibility of syphilitic infection prominently in the mind of the examining physician, and when practicable a syphiligraphist should be in actual attendance at the ante-natal centre. Dr. Ferguson pleaded that a systematic campaign against congenital syphilis should be a routine function of the public health department.

#### *Venereal Disease in the Navy*

Half a dozen papers were read on the welfare of seamen from this point of view, and Surgeon Captain T. B. SHAW, R.N., communicated some observations on the incidence and prevention of venereal disease in the Navy. He pointed out the steady drop in incidence in the Navy up to 1915, and that now, once again after a rise stimulated by the war, the figure was falling to pre-war level. The percentage rate of gonorrhoea was increasing. Fifty years ago gonorrhoeal infections accounted for about half the total but 72 per cent of the cases entered on the sick list for venereal diseases in 1924 were due to gonorrhoea or its sequelae. This was due largely to the fact that no specific treatment for gonorrhoea had as yet been evolved. Of the stations China had the highest incidence of venereal disease and the home station the lowest. He discussed means of prevention in the Navy including education, local disinfection, early diagnosis and treatment, recreation and physical training, quarantine and restriction of leave.

A large proportion of the papers read at the Congress had to do with the state of affairs in India and other parts of the Empire, and on another page we refer to Sir Frederick Lugard's contribution on the training of the African in medicine which if a little aside from the main theme of the congress is interesting especially in view of Sir Frederick's long record as an administrator of British protectorates.

## THE LONDON MOTOR SHOW.

### MORE POINTS FOR MEDICAL MEN

By H. MASSAC BUIST

A FURTHER study of the motor-car designing, manufacturing, and marketing situation as it is revealed at the Exhibition which closes at Olympia, Kensington, at 10 p.m. on Saturday evening next, October 22nd, reveals an average slight reduction in prices, although it had been given out at the end of last summer that these would tend to rise. Inasmuch as vehicles costing less than £150 have been available for over a season, a more practical point is that machines are being offered in a still wider variety of forms, many of which will appeal to the medical man.

### NIGHT SERVICE PROBLEMS AND SOLUTIONS

Take the question of night driving. The dipping headlight device is employed to proportionately a greater extent for the sufficient reason that no "dimmer" scheme is really effective against dazzle, whereas the dipping headlight is a convenient compromise. It gives clear illumination when that is practicable, yet it enables the considerate driver to spare oncoming traffic or pedestrians from being dazzled by his approach. Hence some of the largest as well as some of the smallest cars are fitted with dipping headlights. Among those that are not, however—and these are the majority of standardized products—nearly all have a dimming device of some sort. Although these have been developed in detail it cannot be recorded that any one solves the problem. Curiously enough, one of the likeliest solutions—namely, the momentary drawing of the bulb in and out of focus by Bowden wire control—has not been taken up by the industry. But the new Lucas scheme of tilting the reflector, and the bulb held in it, by pneumatic means is standardized by several car builders and is both convenient and effective, as is admirably illustrated in the standard equipment of the developed Hillman cars.

A useful device for night driving is seen on some of the new six-cylinder engined Rover models. This takes the form of a light, controlled by a switch convenient to the driver's hand, and set on the near side at shoulder height, at the extreme back of the body. Merely by touching this switch full illumination can be obtained instantly in a rearward direction. This is very convenient in manoeuvring in a garage, and particularly in strunge and circumscribed areas, as when backing in a patient's carriage-drive.

But one notices that for the most part illumination of the instrument board is either neglected or is done on an unsatisfactory system, as by having an ordinary top light. Why this should be so—seeing that in several American and in a minority of British and Continental examples the instruments on the board can be illuminated by diffused light, whereby only the face of each instrument shows up and there is no reflection in the driver's eyes—is a mystery. The system most generally exploited on European and even on American constructions really illuminates the floor-board and, particularly, the change speed gear lever, which is quite unnecessary, since the light radiates from the face of most of the instruments. Nor does the diffused light scheme, which solves the problem, lead to extra expense. It is merely a matter of designing the floor-board to take it as a standardized fitting. It will be appreciated that when the face of an instrument only is lit up a clearer result is obtained for an equal volume of illumination. It is also important from the driver's point of view that inside the car there should be no reflections of light to the prejudice of his clear vision of the road ahead and of the surroundings on either side.

As regards car types, undoubtedly the vogue for covered coachwork will enjoy the greater patronage through the introduction of roofs that slide or are otherwise partly removable. They are even likely to have in effect on the demand for landuletto type bodies because the latter are apt to develop leakage, greater or less, with long use. But with some of the sliding, non-tilting roof schemes there is no such likelihood. Further, should any small part get damaged or worn, permitting a leak, it is very cheap and easy to make good. But experience so far does not

indicate that in the best and most practical of the arrangements there is likelihood of any such wear or damage.

### SILENCING

Noise, which is one of the great problems of the car in all forms of human enterprise, has been receiving attention as regards engine exhaust. The chief method exploited for achieving quieter car running is to employ lower geared back valves, which is rather a means of evasion than a solution. Unfortunately, in general the question of the noise of the exhaust has not been sufficiently investigated. It is to be hoped that heed will be paid to the Home Secretary's recent memorandum on this matter.

Admittedly, silencing the exhaust presents quite a pretty problem. Thus, although the intake manifold from the carburettor the gas is drawn into the cylinders at a regular rate. But for every cubic foot that so enters about 5 cubic feet of gas will issue from them, by reason of the much higher temperature of the exhaust at the moment of its expulsion. Therefore its passage through the exhaust pipe has to be very much faster than the intake of the gas, which is, nevertheless, also very rapid. Moreover, the exhaust does not issue from the engine in an even flow, like the feed from the carburettor, but in a series of blasts. Theoretically the easiest way of solving the problem would be to reduce suddenly the temperature of these burnt gases and, therefore to shrink their volume before they enter the silencer. But there is nothing in the current motor-car show at Kensington to suggest that that theory has been worked out in a practical fashion and the result incorporated in standard car practice. All the cars shown have conventional exhaust boxes. More might be done, one would think, by employing at least a fish-tail silencer terminal in the manner required by the Brooklands Automobile Racing Club's regulations. Undoubtedly the improvement in regard to quiet on the track is quite remarkable since these rules came into force. Yet there one is dealing with a more difficult problem, for the engines are of a higher compression and run even faster than do those of the average touring car. We cannot, of course, add an indefinite number of baffles prior to silencers, because that would merely choke the issue of the exhaust from the engine. The burnt gases must have a free exit from the exhaust ports. But many standardized cars, particularly of the cheaper sorts, could be provided with silencers each having two more baffle plates, and that without prejudice to the functioning of the power unit.

As for noise from the gears, little progress has, on the whole, been made in this direction. What has been attained is due, not to the employment of expensive methods of gear production such as Rolls Royce, Bentley, or Daimler use, but merely to the tendency to use a central, or cheaper, American form of change speed gear. Manufacturers are not to blame for seeming to neglect the problem: its solution always involves high cost on one count or another. In cheap car construction, and even in regard to most full scale chassis, it is not a selling point to have quieter gears, the fact being that "bodies" sell now a days, at least in regard to 90 per cent of transactions. But the industry has the gear problem constantly in mind, and would act promptly if a solution were offered.

### GLAZING AND ACCIDENTS

Apart altogether from the attainment of better vehicles—considered possible in no better degree than by the coachwork, which grinds adherents, and by the mere employment of the one panel windscreen, which is expected to come into far more general use twelve months later—one finds, nevertheless, that in standard practice the various forms of safety glass are not widely used. The best scheme is the best known in this country. On the "Safety" Statute, among other transatlantic cars that used a type of glass which appears to have been first used at intervals horizontally through it, and incorporated entirely within the sheet, so that one can see as it were, with a windscreen scored for venting rain. The objection to the former is that it does not give the view in full natural colours, to the latter, the view of fine roads divides the roadscape.

As to glazing no form of safety glass has yet been devised which is as transparent as ordinary glass, and flexible or unbreakable glass is still in the experimental stage. Therefore one notices in some coachwork constructions this and that the front panel or windscreen is made of ordinary glass and that safety glass is used for the rest of the glazing. This is not a mere conceit to the natural desire to behold scenery as it is, it is also based on the fact that, as regards full scale cars, at least, the experience of the repair shops of most of the big manufacturers reveals the lead on collision as the exception rather than the rule, most of the damage being done to the side or rear. Therefore, it is argued, it is not so important to have the windscreen of safety glass as to have the windows made of it.

#### PROMINENT NEW CAR TYPES

The surprise created by the announcement that General Motors' English factory, the Vauxhall Company, of Luton, had introduced a 20/60-h.p. six-cylinder engine car built on an output basis of 10,000 a year—and for which it is understood that the General Motors Corporation which will market it overseas has placed an order for 15,000—is followed this week by the announcement of a larger Morris model, in other words, the arrival of the inevitable six-cylinder engine Cowley built car. While this is something in the nature of a harem machine for the specialist or for the medical man who has to make frequent long distance journeys, nevertheless the average medical man will observe two things: first that this is not a cheaper Morris car, and secondly, that it does not make the six-cylinder engine available for Morris cars of the 11.9 and 14/28-h.p. types. Instead it is a 17.7-h.p. machine of approximately the same engine volume as the new 17-h.p. Fiat which comes in "the two litres and a bit" class. Therefore an even greater number of medical men will be interested in the lowering of the Morris prices in respect of the four-cylinder engine car which are shown also in improved condition, with four-wheel braking on all types. An interesting example of the all-steel body, cellulose finished is the 14/28-h.p. Morris-Oxford saloon in elaret at £250. This model is well worth the extra money in spite of the remarkable value of the 11.9-h.p. Cowley type, which is available as a four-door coachbuilt saloon at £185—a well ventilated vehicle with good visibility. Beige is the new coachwork colour introduced for these cars. It is illustrated effectively in the 11.9-h.p. Morris Cowley four-door four-seater listed at £152 10/- with four-wheel brakes. The tool accommodation has been improved.

Perhaps the Standard Motor Company's announcement of wide interest concerns its re-entry into the light car field with a 9-h.p. four-cylinder side-by-side valve engine machine, which is shown with a four-seater body and also as a fabric saloon, Standard being a recruit to this system of covered body construction. The taxation rating of this vehicle is £9 a year, the side-by-side valve engine having 1154 c.c.m. cylinder volume. The chassis is listed with tyre, tools and spares, at £165. The four-door four-seater is catalogued at £190 complete and the saloon on the same chassis at £215 complete. Unit construction is employed for the engine, clutch and gearbox. The design may be studied in detail, because different parts of the assembly are shown separately. They are sturdy. The complete cars reveal that Standard adheres to its praiseworthy policy of providing roomy accommodation giving in the 'Falmouth' fabric saloon as well as in the 'Selby' open four-seater ample width and leg room for four tall adults. It is understood that at the end of the month a two-seater type with a dickey, will be available though it is not shown. In regard to this firm's other exhibits of six-cylinder engine types it is observable that they are now available, at choice with a gearbox giving four speeds forward, among other variations from the earlier model. The "Folkestone" six-light fabric saloon on the re-rated six-cylinder engine 18/42-h.p. four-speed model has two additional lights, and a front seat adjustable as to both leg reach and angle of back rest. The exterior is pleasing in outline, having a well rounded roof and rear corners, there is a single panel windscreen hinged at the top and having a central adjustment within reach

of the occupants of either of the front seats. The bonnet is finished with cellulose. The price is £440 complete. Corresponding coachwork on a three-speed chassis is listed at £395 complete.

The extraordinary progress made in motor manufacturing is well illustrated in the 12/24-h.p. all-steel Citroën four-door saloon do luxe with rounded back and curved window frames, separately adjustable front seats, and triple cellulose finish, at £225, the chassis embodies sundry refinements such as oil and air purifiers, a very neat steering wheel, control for the lamps and horn, an electric starter button on the facia-board and so on. The point of this development is that here we find a big scale manufacturer making no attempt to offer the lowest priced car on the market by process of economizing this way and that. Instead, the product has been improved certainly out of recognition if we measure progress in this case during so brief a period as twenty months only. Mechanically, the design is vastly better artistically the complete car suggests that its cost must be at least £100 more even when put in competition with American prices, and as regards accommodation this is now ample.

How many people are aware that about 12,000 parts go to the making of one of these chassis, which are among the simplest on the market? From now on every part in this chassis is displayed separately without fee, at Devonshire House, where also the mechanically minded and those who know nothing of such matters may learn "the anatomy of the motor car." In this case the average price of a car part from cylinder casting to a split pin is about fourpence. Here the visitor may see even the components of electrical accessories including engine starting and ear lighting equipment the various processes of building all steel bodies, the different stages of cellulose finishing all the components of the upholstery scheme, and the extraordinary number of parts which it is possible in big scale production programme to make strong, light, and simple by pressing processes.

An idea of the variety of the new style of cars offered by established manufacturers may be indicated in tabular form, thus:

Maker	Country	Cylinder		H.I. Rating	Annual Tax	Price	Body Type
		No.	Vol.				
Alvis	Br	6	c.c.m.	17.5	£5	£595	Open 5-seater
Armstrong	Br	6	1913	15	1s	400	Saloon 4-seater
Arrol-John	Br	6	3018	21/0	21	750	Saloon 5-seater
Austin	Br	6	2,4	15	15	350	Saloon 4-seater
Bean	Br	4	2,37	14	0	320	Saloon 4-seater
Bentley	Br	4	4,33	21.8	25	1,250	Open 4-seater

La Salle	U.S.A.	4	9,57	—	32	325	Saloon 4-seater
Lea-Francis	Br	6	1,695	14.0	14	600	Saloon 5-seater
Marmion	U.S.A.	8	3,110	—	2	600	Saloon 5-seater
Mercedes	G	6	6,2	33.0	33	2,150	Saloon 5-seater
Morris	Br	6	—	17.7	—	—	—
Peerie	U.S.A.	6	3,25	32.62	6	475	Saloon 5-seater
Pengoe	Fr	6	1,921	15.7	15	325	Saloon 5-seater
Renault	Fr	6	1,427	12	13	290	Saloon 5-seater
Piley	Br	4	1,037	9	10	425	Saloon 4-seater
Rover	Br	6	2,025	—	16	425	Saloon 5-seater
Standard	Br	4	1,154	9	9	215	Saloon 4-seater
Star	Br	6	2,453	18.50	18	49	Saloon 5-seater
Triumph	U.S.A.	4	6,37	—	40	1,500	Saloon 7-seater
Vauxhall	Br	4	1,37	19	8	190	Saloon 4-seater
Volvo	Br	6	2,2	19.0	20	425	Saloon 5-seater
Volvo	Br	4	1,533	17.5	17	315	Saloon 5-seater
Volvo	Br	8	2,814	21.0	21	750	Saloon 5-seater

The specification of the new 6-cylinder engine Morris had not been issued at the time this article went to press, the cost of the chassis is £21 of the 5-seater version £320 of the 5-seater saloon £320. Some American manufacturers do not give their cars any h.p. ratings.

Owing to changes of price and equipment details at the last moment, in some cases it is impossible to ensure that every particular set down holds at the time of publication. But every care has been taken to achieve accuracy.

SATURDAY, OCTOBER 15TH, 1927.

## TREATMENT OF PERNICIOUS ANAEMIA

ARSENIC as a therapeutic agent has undergone many vicissitudes since Hippocratic days. Its reputation became slightly sinister when La Spina sold it to the young matrons of Rome as a cure for their matrimonial troubles, and it fell into complete disgrace when its use as a secret poison became widespread in other circumstances. Nevertheless it has survived these abuses, and in pernicious anaemia it has been recognized as the one drug which has some benign influence on the course of the disease. Professor Gulland, opening the discussion in the Section of Medicine at Edinburgh on the pathology and treatment of pernicious anaemia, of which a report appears at page 669, goes so far as to assert that in this disease arsenic is still our standby. Its action, however, is uncertain, it is too often transient and ineffective, and so it is not surprising that other methods of treatment have been tried from time to time, though until recently without much definite success.

Many of these therapeutic procedures owe their origin to the commonly accepted doctrine of the pathogenesis of the disease, which declares the primary fault to be a toxæmia resulting in an excessive haemolysis, some of them have involved dietetic measures with a view to lessening abnormal bacterial activity in the alimentary canal. Attempts have also been made to stimulate the activity of the bone marrow by some form of general forced feeding, or by including in the diet some special substance, such as marrow, which might act specifically on the haemopoietic function. Additional interest was given to these efforts by the experimental work of Robscheit-Robbins and Whipple,<sup>1</sup> who showed that the administration of beef liver to dogs with severe experimental anaemia markedly increased the rate of blood regeneration. No very striking clinical results were evident until Minot and Murphy<sup>2</sup> of Boston published their first paper on "The treatment of pernicious anaemia by a special diet" in 1926. The essential part of their procedure was the inclusion in the daily diet of 120 to 240 grams of cooked liver, and the results which they have obtained in a series of 125 cases observed over a period of one to three years will be found in Dr. Minot's paper printed at page 674. Briefly, their experience is that in practically every case where the liver is satisfactorily ingested the red cells and the haemoglobin regenerate rapidly, the patients recover their health, and no relapses occur while the diet is being taken. In a smaller series of cases examined in greater detail it was shown that the blood picture returns to normal under this treatment, and, in particular, that the curve of the diameter of the red cells is no longer of the abnormal type shown by Pucc-Jones to be characteristic of pernicious anaemia. These observations, especially when taken in conjunction with Peabody's investigations on the bone marrow, suggest at first sight that the diet has some direct action on blood formation, they will therefore be very closely scrutinized by those whose investi-

tions have led them to discard faulty blood formation as the primary lesion. Nevertheless, there has been a considerable amount of confirmation by other workers, and there appears to be agreement that liver diet is frequently accompanied by most beneficial effects, there is already a gradually increasing number of patients in this country who have made a very gratifying response to the treatment without relapse. In these, as well as in Minot's cases, time alone will show how permanent the effect is. In this country the scattered results, which are all that are as yet available, do not seem to be quite so uniformly good as those of the Boston series, for one thing, there is apparently greater difficulty in getting the patients to take the rather unpleasantly large quantities of liver, and in some cases there has so far been definite failure to respond even to adequate diets. These difficulties may be overcome with more experience, we are admittedly a long way behind our American cousins in the art of preparing special diets in a palatable form, and when the deficiency is recognized it may be speedily remedied. Attention was drawn to the possibility of combining fresh calf-liver with anchovy paste in sandwiches (*Epitome*, October 1st, para 291), and in the issue of the *Journal of the American Medical Association* for September 17th, under the intriguing title of "A liver cocktail," there appears a recipe which includes tomato catchup, lemon juice, Worcester sauce, and chives. It is mentioned, however, that time must be allowed each patient to "develop a taste" before large amounts are added. It may also be possible before long to replace whole liver by an extract, since Cohn<sup>3</sup> has already succeeded in isolating a non-protein fraction which has given comparable therapeutic results, as was stated more at length in a leading article published a fortnight ago (October 1st, p. 603). It is, however, not necessarily fair to expect all cases to respond to one form of treatment, though Minot and Murphy suggest that if a patient does not react to liver diet the case is not one of pernicious anaemia. Looking at the matter from this angle, it may be that pernicious anaemia has yet to be subdivided into several groups of different etiology, we already know that the typical pernicious blood picture is seen in sprue, bothrioccephalus infection, and in obstruction of the small intestine, and there may well be other groups, some of which respond to liver diet while others do not.

Although Minot's investigations provide us with the most outstanding results in the treatment of pernicious anaemia to day, there are others which possibly merit a place in practical therapeutics, and which may serve as a signpost when the time comes to consider what bearing the therapeutic results have on our views as to etiology. In some investigations of the toxicity of certain blood serums for plants Macht<sup>4</sup> found that the serum of patients with pernicious anaemia was peculiarly toxic for certain seedlings. He subsequently discovered that irradiation with ultra violet light detoxified the serum, enabling the seedlings to grow as well in it as in normal serum, moreover, this effect was intensified by sensitization with various dyes. Practical application of this work showed that the treatment of patients with pernicious anaemia by ultra violet light, particularly when combined with the administration of eosin, was attended by promising clinical results. The serum of these treated patients showed very definite improvement as judged by the phytopharmacologic test, the serum of patients ir-

with liver diet alone sometimes showed a similar response but in other cases a marked toxicity persisted in spite of the diet.

The intelligent use of any new therapeutic agent must include a consideration of its bearing on the etiology of the disease, and these new methods of treatment of pernicious anemia undoubtedly open up fresh ground for debate and new paths for experiment. At first sight they may seem to be opposed to the older views. When this is the case we must proceed with caution, remembering Professor Wenden Bergh's warning that newly established remedies must be correlated with the old they cannot replace them. Here, however, we need only call attention to the much more hopeful outlook now of the treatment of a disease which has hitherto marched sometimes quickly—sometimes with halting steps—but almost always inevitably to a fatal end.

### THE TREATMENT OF FRACTURES

At the last annual session of the American Medical Association, held in Washington, the chairman of the Section of Orthopaedic Surgery, Dr. John Prentiss Lord of Omaha, chose for his subject the advancement of orthopaedic surgery. After giving a short sketch of the history of orthopaedic surgery he went on to raise and discuss the interesting question of the treatment by general surgeons and practitioners of fractures and some other injuries, and he pleaded with much force for the specialization of this branch of practice in the hands of orthopaedic surgeons.

The interest of Dr. Prentiss Lord's address is much enhanced by quotations from replies to a questionnaire which was addressed to various surgeons throughout the United States concerning the status of orthopaedics in the leading universities. The writers of these replies are all or nearly all engaged in the teaching of surgery as a whole, and not specialists. Their evidence is therefore not to be suspected of any bias in favour of specialism. It would appear from these quotations that there is a widespread tendency in America to associate orthopaedic specialists with general surgeons in the treatment of fractures by some such scheme as that known as the Fracture Service at the Massachusetts General Hospital in Boston which was described in the book on fractures by Dr. Wilson of Harvard and Mr. Cochrane of Edinburgh<sup>2</sup> while at the Mayo Clinic according to Dr. M. S. Henderson the orthopaedic service handles all the fractures both recent and old and all the joint conditions both acute and chronic.

This question was debated at length at a joint meeting of the Sections of Orthopaedics and of Surgery during the Annual Meeting of the British Medical Association at Bath two years ago when even such a deprecator of specialism as Mr. Gask said that he would welcome the foundation of a special hospital in London for the treatment of fractures under the care of specialists, a hospital in which the best methods could be shown and from which light would spread. Since that time nothing—so far as our knowledge goes—has been done to reach the consummation which was acknowledged at Bath as so devoutly to be wished although with the steadily increasing stream of motor accidents it each year becomes more desirable. It may not be a good time for the foundation of another hospital in London but a beginning could

surely be made by setting aside wards in an already existing hospital for the treatment of recent fractures and the prevention of deformities resulting from imperfect treatment. Such a hospital or such wards would set a standard for all surgeons to aspire to emulate and would prove of incalculable benefit to the community at large by reducing the amount of suffering and disability caused by fractures.

One of the stock arguments used by the opponents of specialization is the fear that by transferring any department of surgery from the general surgeon to the specialist the student might become indifferent to the specialty and cease to receive instruction in it. This might possibly be true of some special department already existing but it is in our judgement a baseless fear as regards the treatment of fractures. The plain fact is that as things are at present in London the student gets little instruction in the treatment of fractures of the upper extremity and no experience in the treatment of the much more important fractures of the lower extremity for the simple reason that such cases are not usually admitted to the wards of the great teaching hospitals. The demand for beds in these institutions is so urgent that acute diseases and conditions affecting the cavities of the body have preference and abdominal sections, which can be sent to convalescent institutions or to their own home a fortnight after operation occupy the beds used for fracture cases which would probably on the average require at least six weeks' treatment.

### LORD IVEAGH AND THE LISTER INSTITUTE

The memory of Lord Iveagh the head of the Guinness family who died on October 7th in his eightieth year, well deserves to be cherished by the medical profession especially those who are interested (and who is not?) in the prevention of disease through the study of pathology. The greatest proof of his own interest in this department of theoretical and applied science was the gift by which he put the Lister Institute in a sound financial position. Sir Charles J. Martin the director of the Institute, has been good enough to write the story for our readers in the following words: "Lord Iveagh" he says, "was in the habit of sharing a good deal of his wealth with his fellow men. In doing this he exercised discrimination, and continued to interest himself in the administration of his various benefactions. All of them were directed to the betterment of our social organism and particularly to the improvement of the conditions under which the poorer members of the community have to live. Lord Iveagh also made large donations to Trinity College, Dublin, and to the hospitals in that city and elsewhere but it is as the largest individual contributor of our generation to the endowment of medical discovery in the British Isles that he is distinguished. In 1898 he gave £250,000 to the Lister Institute of Preventive Medicine then the Jenner Institute, and about ten years later he in conjunction with the late Sir Ernest Cassel provided the funds for the creation of equipment and endowment of the Radium Institute in Rider Street for the prosecution of research into the possibilities of radium as a therapeutic agent and for the treatment of patients whose means did not permit of their receiving the benefits of radium treatment without financial assistance. From a conversation I had with Lord Iveagh many years ago I gathered that the idea of endowing medical research occurred to him originally owing to the circumstance that a labourer upon his estate was bitten by a rabid dog. Lord Iveagh was informed of the accident and directed that everything possible was to be done for the unfortunate man, but was surprised to learn that the

<sup>1</sup> See also in the *Advancement of Orthopaedic Surgery* *Journal of the American Medical Association* vol. 40, no. 6, p. 652.  
<sup>2</sup> *British Medical Journal* 1925, vol. 1, p. 323.

prophylactic treatment for hydrophobia could only be secured by sending the patient to Paris. This was done, and no further ill results ensued, but the novelty of the treatment and the absence of facilities in England for the prosecution of researches such as had led to Pasteur's fruitful discovery, made a deep impression on his mind. In 1898 Lord Iveagh visited the Pasteur Institute, and the project of endowing a similar institute in London began to take shape. He consulted Dr. Thoinot Thoinot, the principal medical officer of the Local Government Board, who pointed out that there was an institution with the objects he had in view—the Jenner Institute. It had recently erected a good building on the Chelsea Embankment, but was so short of funds that its activities were severely limited. Dr. Thoinot suggested that it might be wiser to help the Jenner Institute than to found another separate institution. Lord Iveagh visited the Jenner Institute, and subsequently interviewed its chairman, Lord Lister, and Sir Henry Roscoe, its treasurer. At the interview Lord Iveagh was accompanied by his private secretary, Mr. J. Luard Pattison, who afterwards became the honorary treasurer of the Institute and was for many years one of its best friends. They made searching inquiries concerning the ideals, administration, and financial position of the Institute. Some years afterwards Lord Lister described this interview to me as a very critical examination, and was quite sure he had failed to satisfy the examiners. However, before many months were past Lord Lister, to his surprise and gratification, received an intimation from Lord Iveagh that he desired to endow the Institute to the extent of £250,000, subject to certain alterations in its constitution and government. The Lister Institute is doubly indebted to Pasteur's discovery of the treatment of hydrophobia. It owes its inception to a meeting at the Mansion House in 1889 to present M. Pasteur with a grateful acknowledgement of his gratuitous kindness to 200 British patients bitten by rabid animals, and its chief endowment to the impression made upon a receptive mind of the possible benefits to mankind of researches such as those which led to the successful combating of this dreaded disease."

#### MEDICAL SERVICE IN MANDATED AFRICA

SIR FREDERICK LUGARD, formerly Governor-General of Nigeria, who was one of the sectional presidents at the Imperial Social Hygiene Congress held in London last week, made some interesting remarks on medical problems in those huge rivers of Africa which are now under British administration. He said that while the British Government had declared that it regarded itself as exercising a trust on behalf of the African population, it was difficult, if not impossible, to get the medical staff required. He quoted Mr. Omsby-Gordon, Parliamentary Secretary for the Colonies, as reporting, after his missions to East and West Africa, that he had found a district in which there was a single medical officer in charge of three-quarters of a million natives. Even before the war, when Britain had not assumed the great added responsibility of the mandated territories, it was not easy to obtain the medical staff required, and the matter was so important that it was worth very earnest attention. But Sir Frederick Lugard went on to speak of another deficiency which was graver, and which ought to be more easily remediable—namely, the lack of a trained African staff. In his view there ought to be a steady supply of Africans trained in four categories: (1) hospital attendants, (2) sanitary inspectors and dispersers, (3) subordinate medical officers, and (4) fully qualified medical officers. These needs could only be met, he said, by popularizing the profession of medicine among those attending the secondary schools, and by assuring appointments to those who qualified for either of the last two grades. He was afraid there was no hope at present

of seeing trained Africans serving as private practitioners in rural districts, for the Britisher's preference for a congenial and much more lucrative European practitioner. But until this is changed, it is premature for him to talk of self-government. Speaking as a member for the British Empire of the Permanent Mandates Commission of the League of Nations, Sir Frederick Lugard said that two schemes of medical service had attracted his attention in that Commission, and possibly medical officers abroad might regard them as worthy of consideration. The first was the medical patrol adopted by Australia in its mandated territory of New Guinea. This patrol toured slowly from village to village, equipped with a van containing all the necessary apparatus and drugs. The other was a system adopted by Belgium in its mandated territory of Ruanda, whereby a few selected natives were trained up to a standard approaching professional skill in the treatment of a very limited number of prevalent diseases. These men were then sent for a year's work among the rural population, after which they returned for a renewed training at headquarters. As vaccination, and in the treatment of venereal diseases and of hookworm, as well as in propaganda with regard to preventive measures against insect-borne diseases, such men, said Sir Frederick Lugard, might do much good, and the information which they brought back was likely to be of service. The conference of governors of British dependencies, which took place in London last May, expressed the view that "no activity of government is more likely to win the confidence of the natives than successful medical work", confidence could better be won by providing an adequate professional and subordinate staff which understood the native and could speak his language, which was constantly touring the villages, and was not liable to frequent change, than by building fine hospitals which were shunned by the natives, and which could not be staffed except by depleting the district of its doctors.

#### CONGENITAL STEATORRHOEA

CONGENITAL steatorrhea, in which the faeces contain oil that solidifies on cooling, was first described in 1913 by Sir Archibald Garrod and Dr. W. H. Hurley.<sup>1</sup> The condition is very rare, and it was not until 1920 that a second case was placed on record by Drs. R. Miller and H. Perkins.<sup>2</sup> A third case has now been detected by Drs. A. Soehnle and F. Thoenes,<sup>3</sup> who describe the condition as familial insufficiency of the pancreas based upon a constitutional anomaly; they definitely relate it to the congenital steatorrhea of Garrod and Hurley. A brief note on this third case had been previously published by Thoenes.<sup>4</sup> The patient, a boy, was 17 months old on admission to hospital, an elder brother (who was mentally deficient) and a sister had similar fatty stools. The mother had noticed the peculiar odour of the faeces and their fatty content when the child was aged 13 months. Investigation showed that there was optimum utilization of the carbohydrate, with much fat wastage, and a negative nitrogen balance, owing to loss of this element in the stools. The fat excretion was restrained and the nitrogen balance restored by the administration of "pankicon." There was also in this case cretinism—passage of meat fibres in the stools when a meat diet was employed. Although Soehnle and Thoenes definitely associate their case with those previously recorded, there are some differences, for in the two first instances no evidence was obtained of failure of true digestion, although Garrod and Hurley suggested pancreatic insufficiency as a probable factor. In this third case the patients were first cousins, and Garrod and Hurley

patient, a boy, was also the offspring of a marriage of first cousins, his younger brother, who had been similarly affected, had died from measles at the age of 18 months, but three other children in this family were normal. The parents of Miller and Perkins's patient were not related. No post mortem examination was held in any of these cases, but it may be noted that Passini described in 1919 the case of two children in a family who died at the ages of 9 months and 2 months. During life the impairment in fat utilization was conspicuous, and the necropsy revealed atrophy of the islands of Langerhans, with cystic degeneration of the shrunken pancreas. Passini's cases show that gross changes in the pancreas can occur at a very early age, but without an adequate clinical investigation it was not possible to decide whether they were examples of congenital steatorrhea. The occurrence of several cases in a family with normal but consanguineous parents tends to confirm the view that it is a Mendelian recessive condition.

#### LEAD PAINT FOR BUILDINGS

In 1911 the Home Office appointed two departmental committees to investigate the incidence of lead poisoning among persons employed in painting buildings and vehicles. Both committees recommended that the use of lead compounds should, with certain minor exceptions, be prohibited for all work. In 1921 it was agreed at Geneva that white lead and lead sulphate and their products, with certain exceptions, should be prohibited, not in the internal painting of buildings only. In the meantime controversy had arisen on the recommendations of the two departmental committees, and the Home Office, in 1921, had appointed another committee, which declared itself against the departmental committees and in favour of the Geneva convention. In the end the Government decided that regulations should be tried in preference to any prohibition. The Lead Paint (Protection Against Poisoning) Act was passed in 1926. It empowered the Secretary of State to make regulations preventing danger from lead paint in connection with the painting of buildings, including fixtures. The Lead Paint Regulations, 1927, made under the Act came into operation on January 1st. Among their chief provisions are (1) that, unless for stopping or filling, lead may not be used for the painting of buildings except in the form of paste or paint ready for use; (2) that the lead sprays may not be used inside buildings; (3) that no lead painted surface other than iron or steel work may be rubbed down or scraped by a dry process and that no lead painted iron or steel work may be rubbed down or scraped by a dry sandpapering process; (4) that there shall be provided for the use of employees sufficient washing facilities; and (5) that arrangements shall be made to prevent clothing taken off during working hours from being soiled by lead paint. Provision is made further for the periodical medical examination of all employees if the incidence of lead poisoning is excessive. Employees are required to wear overalls, to protect their ordinary clothing from lead paint, to use the washing facilities provided and to appear for medical examination when required. The Act excludes women and young persons from the work, with some exceptions. An instructive commentary on the regulations is supplied in a recent Home Office report by Sir W. W. Mackenzie. The dust set free by the dry process of rubbing down old paint with a view to repainting has been one of the chief sources of lead poisoning in the past. This process is now required to be done in the wet and a waterproof sandpaper is available. Iron and steel work may still be prepared for repainting by the dry method. The chipping hammer employed liberates scales of lumps not dust, and the wire brush, also employed, has not yet been proved to have caused lead poisoning. The provision which figured in the draft code, that five minutes should be allowed to each person for washing before each

meal time and before leaving work, has been deleted in the regulations as issued, and is left to be dealt with by mutual agreement between employer and employee. The Lead Paint (Protection Against Poisoning) Act may be criticized by some on the ground that it falls short of prohibition. It may, on the other hand, be justly claimed that it strikes at the principal sources of danger in the painting of buildings, the process with which it deals. In any case, it is to be regarded as experimental. If it fails the Government is prepared to bring in prohibition.

#### BRITISH INSTITUTE OF RADIOLOGY

THE negotiations for the amalgamation of the Röntgen Society and the British Institute of Radiology, which were initiated by Sir Archibald Reid before his lamented death in 1924, have now been brought to a successful conclusion, and the event will be celebrated in London next month. The object of the Röntgen Society, the first radiological society to be established, was to promote the study of radiation from the physical side, it included medical men and manufacturers of apparatus, as well as physicists. The British Association of Radiology and Physiotherapy, founded some years later, consisted of medical practitioners. In forming the British Institute of Radiology Reid had a vision of a central clearing house for all things pertaining to x-ray work, where every aspect of it, including its application to medicine, engineering and other practical matters, could be combined and co-ordinated. In order that the Institute should have a local habitation, where its members could meet and where lectures and instruction could be given, he made himself responsible for the purchase of the house the Institute now occupies in Welbeck Street. The combination with the Röntgen Society is a great step forward, we heartily congratulate the promoters on it, and have no doubt that the combined body will make important contributions to science and practice. It should be noted that the Society of Radiographers will continue to be affiliated with the society now established. The celebration of the amalgamation will begin on Thursday, November 17th, when Sir Humphry Pollard, Bt., M.D. (President Elect of the new body) will give an address at a general meeting to be held at 2.45 p.m. at the Central Hall Westminster on the following morning there will be discussions on x-ray and radium protection, and on an international x-ray unit. In the afternoon the value of opaque injections as an aid to x-ray diagnosis in disorders of the nervous, urinary, and pulmonary systems, and in gynaecological conditions, will be dealt with. In the evening there will be a dinner at the Great Central Hotel, Marblebone. The vice presidents of the amalgamated body are Sir William Bragg, F.R.S. Dr. Alfred F. Bridley (Manchester), Mr. Thurstan Holland (Liverpool), and Dr. Robert Knox (London). The honorary treasurer is Dr. S. Gilbert Scott, and the secretary Dr. John Muir, from whom, at the house of the British Institute of Radiology, 32 Welbeck Street, London, W.1, further information can be obtained.

#### HEROISM IN THE SHIP SURGEON

STOICISM'S appreciation of the medical man is not common in the lay press. The *Journal of Commerce*, published in Liverpool, has, however, been struck by the frequency of reports of assistance rendered by the ship surgeon to sick or injured members of the crew or a vessel other than his own. Our contemporary is surprised that so little, if any, public recognition is given to these services, and it has devoted a leading article to the praise of this admirable officer. The state of affairs is compared with the publicity and awards which accrue "from other forms of life-saving at sea," and it is asserted that the risks undertaken by the ship surgeon—who is not trained in the seaman's facility for "hanging on by

his eyebrows"—in transferring a sick or injured person to the hospital of another ship, and often just as serious as those incurred in rescuing men from a sinking ship. In addition to this, the ship surgeon has much preliminary work in communicating by wireless appropriate treatment while the ships are converging, and he may be called upon to perform an immediate operation under the difficult conditions which are unavoidable at sea. The *Journal of Commerce* suggests that the Royal College of Surgeons or some similar body should undertake the task of according recognition to the devotion to duty shown by ship surgeons. The body named may not be appropriate, at the same time, there seems no reason to think that our contemporary is right in supposing that the etiquette which hedges the medical profession is a deterrent to the honouring of its worthy members. It is pleasing to learn from correspondence published in later numbers that shipmasters and others concur with the views expressed by the *Journal of Commerce*.

#### EXCLUSION, NOT CLOSURE

THE general improvement of living conditions in this country which distinguished the course of the nineteenth century, and continues even more notably during the twentieth, has led to the reduction or abolition from our midst of a number of communicable diseases which had been the standing or recurrent scourges of previous ages. Medical science has impressed on the public the importance of pure water, household cleanliness, or restriction of overcrowding, the benefits which have resulted from them are manifest. Some epidemic diseases, however, including not a few of the most common—like measles, diphtheria, and scarlet fever—have proved intractable in the face of hygienic progress. These diseases, transmitted by spray infection, are usually highly infective, and are liable to spread on the ordinary occasions of life wherever people meet together. They are for the most part infections of childhood, and the gathering of children together in schools has long been thought to offer facilities for their transmission. During the earlier currency of the legislative measures for the control of infection mass action was favoured in dealing with schools. If the infection was slight or incipient no effective steps were taken, when it became substantial the whole school was closed, greatly to the detriment of the primary object for which the school existed, and frequently without the slightest effect in checking the spread of the malarial. The modern policy of exclusion, not closure, which endeavours to focus on the individual child, is well portrayed in the Memorandum on Closure and Exclusion from School, issued jointly by the Ministry of Health and the Board of Education, in which the following sentence occurs: "If, during epidemics of infectious disease, the power to exclude individual children from school be used to the best advantage, it is only in special and quite exceptional circumstances that it will be necessary to close a school in the interests of public health." The memorandum urges that the problem of school infection can be successfully approached only in the knowledge of the natural history of each disease, and after inquiry into the special circumstances of each child concerned. The principal diseases are taken up in order, and the rules of procedure stated for each. The difficult questions raised by the infectious diseases of the central nervous system are helpfully summarized. The exclusion of susceptibles is not referred to, it cannot be applied to children living at home and attending public elementary schools. Disinfection of special class rooms on occasion, is cautiously authorized. No reference is made to the general disinfection of schools, which thus receives, although in a tacit form, an obituary notice. Leonard Hill should

concur in this attitude, for he says in his address to the Sanitary Inspectors' Association: "The fumigation of a room after occupation by a case of infectious fever is a futile." The joint memorandum comes with authority, conveying to the mind in succinct and lucid manner what every medical officer should remember and every teacher seek to understand. The statements made have obviously been carefully weighed, and on the medical side are practically flawless. Unless in accordance with the principles of the memorandum, the Board of Education and the Ministry of Health will not accept the closure of schools for reasons claimed to be medical.

#### PROFESSIONAL OPPORTUNITIES OF THE SERVICE MEDICAL OFFICER

LIKE his two predecessors in the chair of the War Section of the Royal Society of Medicine, Surgeon Vice Admiral Arthur Gaskell, F.R.C.S., devoted his presidential address on October 10th to a discussion of the professional opportunities of the service medical officer. He set out to combat the widely prevalent notion that the services offer only very limited professional opportunities. The first opportunity he mentioned was that for reading. The man in civil practice, he said, was almost necessarily condemned to a more or less monotonous routine, with very rare interregnums, whereas the service medical officer's career included spells of regimental work or work on board ship, as the case might be, alternating with periods in hospital, and in his less strenuous periods he had abundant opportunity for reading and study, perhaps with a view to a Fellowship or special diploma. Even apart from this initial advantage of time for reading, the service officer had other opportunities for obtaining higher qualifications. In civil life, once a man was well launched in the practice of his profession he seldom had time, without undue sacrifice, to enter for the higher examinations. But in the services a man might, while still on full pay, obtain special leave for this purpose. The services offered opportunities also for training in methods of clinical examination. In civil practice, except perhaps in the school medical service, a practitioner was not usually able to carry out repeated examinations, and therefore he was denied a certain knowledge of the normal. The service officer, again, had access to a large and varied quantity of clinical material. It might be thought that in large service hospitals, where there was quantity there was not quality, but this was quite a mistake. The patients taken into the service hospital included not only men from the active list, but from the retired list, and a very wide range of material was at hand. The opportunities for major surgery were constant and every branch of specialist work was available, and in connexion with venereal and with tropical diseases opportunities were unequalled elsewhere. Specialists were encouraged in the services, and those who had taken specialist diplomas were given specialist work to do. Service medical officers were given specialist work to do, and were paid specialist allowances. Though the pay of a service medical officer was not high, it did not compare unfavourably with the remuneration of the civil practitioner. He was told that a very successful minor practitioner in an industrial district might expect to receive £1,000 a year by the time he was 30, but it had been remembered that in order to achieve such a result he was compelled to live in expensive surroundings and to devote his time almost entirely to routine. It was only by a struggle that the civil practitioner was able to save from his earnings enough to purchase a pension, and it was to that enjoyed by the service officer, and as the pension was deferred pay the remuneration in the services was not, after all, so disadvantageous. In fact, at the end of the address Lieut.-Colonel Sir Martin D.G.A.M.S. spoke of the way in which the chair of medicine is now concentrated in the large army hospitals.

of being scattered over a number of small units. Air Commodore David Munro declared that in many ways the opportunities given to service medical officers were more varied than those which fell to the lot of civil practitioners, and that the keen man in the service was given full liberty to pursue his opportunities on his own lines. Surgeon Vice-Admiral Sir Joseph Chambers emphasized the value of post-graduate work, the opportunities for which were afforded liberally in the services, and Mr T B Layton speaking as one who had experience of the services during the war, said that one thing of really great value to be learned therein—a thing which the civil practitioner was rather apt to disregard—was the accurate filling in of documents and careful keeping of records.

#### ADOLF KUSSMAUL.

PROFESSOR T H BAX of the University of Wisconsin Medical School has now republished, with additions, his article on Adolf Kussmaul in the *Annals of Medical History*, and thus for the first time supplied in English an account of this distinguished physician, who represented the best German type. Born in 1822, Kussmaul, early in his professional life (1845), worked hard to construct an ophthalmoscope and actually made one but unfortunately it would not work, or he would have anticipated Helmholtz. Believing firmly in the beneficial effects of induced vomiting, which he practised on himself in an illness self-diagnosed as "meningitis lumbalis," he is often credited with the invention of the stomach pump, but it is pointed out that in this he had been anticipated by Dr Dorsey (1809) and the latter's uncle P S Physick, professor of surgery in the University of Pennsylvania (1812), and Jukes (1822), an English surgeon whereas Kussmaul first employed gastric lavage in 1857. It is perhaps worth noting that the two portraits of Kussmaul (1822-1902) in the volume bear a slight resemblance to those of the late Sir Clifford Allbutt, who was one of the first to practise gastric lavage in this country and in 1869 invented a stomach siphon instead of the clumsy and formidable stomach pump. In 1853 Kussmaul was the first to use a gastroscope, and in 1873 described the paradoxical pulse in mediastinopericarditis, which, however, had been previously noticed by Griesinger and recorded by Videumann in 1856. His description of air hunger in diabetic coma often called "Kussmaul's respiration," appeared in 1874. He taught clinical medicine first at Heidelberg then at Erlangen, Freiburg, Strasbourg, and finally, in 1888, returned as emeritus professor to Heidelberg, where he wrote his autobiography. On his eightieth birthday a special volume of the *Deutsches Archiv für Klinische Medizin* containing contributions from thirty-three former associates, was dedicated to him, and a few months later he died after half an hour's agony from what has been called the doctor's disease—an angina pectoris.

As already announced, the Harveyan Oration before the Royal College of Physicians of London will be delivered by Sir William Hale-White K B E, M D, at the College on Tuesday next October 18th, at 4 p.m. It is anticipated that he will deal with the possible influence of Francis Bacon's views and writings on Harvey, and will refer also to the work of Gilbert of Colchester, whose great book *De Magnete* was published in 1600 the year in which he was President of the Royal College of Physicians. It is true that Harvey was then still in Padua but he settled in London only two years later, and the book had attracted a great deal of attention. The annual sermon under the Sadler Trust will be preached in the church of St. Martin-in-the-Fields at noon on October 18th.

## Scotland.

#### PUBLIC HEALTH ADVANCE IN SCOTLAND

DR W E LILLIOT, M P, Under Secretary of State for Scotland, recently addressed a meeting in Eden on the task before the Scottish Board of Health. He said that a healthy people was the greatest asset a nation could have. The Board of Health had a great responsibility in seeing that each generation of children was better than that which had gone before. As a proof of this he said that in Scotland in the year 1840, out of every five children that were born, four died before reaching the age of 1 year. At the present day they could claim that not more than one out of every ten died before reaching the first birthday, and the ideal before the Board of Health was to reach a figure in which fewer than one in twenty would die before reaching age 1. Last year, despite the great trade dispute, was the healthiest when Scotland had ever known. The figures in regard to tuberculosis were so promising that he was hopeful that within twenty or thirty years tuberculosis would, like typhoid fever at the present day, be one of the rare diseases. The real way to fight disease, he said, was by fresh air and plenty of food. Fresh air was represented in housing, and in this respect the Government had a splendid record. In 1924 in Scotland 4,000 houses had been completed, 8,000 in 1925, and 12,000 in 1926, and by the end of the present year he expected that the number would reach 18,000 or 20,000 houses. It would be their housing policy to repeat that figure next year.

#### ROYAL SANITARY ASSOCIATION OF SCOTLAND

At the fifty-third annual congress of the Royal Sanitary Association of Scotland, held recently at Inverness, Dr A S M Macgregor, medical officer of health for Glasgow, delivered his presidential address on "Modern tendencies in public health." He referred to the weakening, observed on all hands, of the resistance to health reforms. Medical science and the humanitarian movement had effectively joined forces, and broad and bold constructive recommendations were being put forward as a result. The need for a complete and adequate medical service, developed on the preventive side, was in principle recognized, and the road along which future progress should be made seemed clear enough. Large ideas of this kind required for their fruition not only the support but the active co-operation of the people, and the people in general were becoming well aware of their indebtedness to medical discovery, and the consequent increasingly high standards of general medical practice. The health crusade was influencing legislation, and had found expression in the new form taken by the Annual Reports of the Scottish Board of Health, in which a vivid and suggestive narrative had taken the place of a statistical compilation. There were some who maintained that much of what was being attempted now was based on a sort of pseudo-science, and went beyond ascertained knowledge. It was true that a large group of diseases—immaturity, debility, and prematurity—classified at present as inevitable causes of infant mortality, had hitherto baffled inquiry. They were, however, being submitted to investigation at the research laboratories of the Glasgow Maternity Hospital. Another inquiry at Glasgow had made it plain that the severity of measles was abnormally great among young children in crowded tenements. This was an ascertained fact, and the sickness and death rate at young ages in congested areas was the main justification for slum clearance schemes. Scientific investigation must precede or endorse well directed public health measures. Bacteriology, for example, had aided in the repression of many diseases, and immunotherapy was its latest development. Physiology, too, exploring the great laws of physical fitness, had furnished principles of the widest significance, which it might take years to put fully into practice. The new Factory Bill from beginning to end was applied physiology. The wide acceptance by the nation of such principles as these was the most important movement in public health to-day. That fresh air, smokeless air, sunshine, good houses, and good ways of living were highly valued by most was due in part

The Life and Times of Adolf Kussmaul. By Thomas H Bax. Ph.D. With a foreword by William Snow M.D. D.Sc. New York: Paul B Hoeber (Inc.) 810 Fifth Avenue, 123, 150 de la Salle.

to quiet sinister propaganda, especially that which radiated from child welfare and tuberculosis clinics and from school medical inspection centres. Where good houses had been provided under slum clearance schemes the proportion of people who were trying to maintain hygienic standards had been above expectation. If any failed it was the local authority's duty to bring them up to standard. Hygiene appealed to the best instincts of mankind and was helping to solve social problems. It was ready to join forces with any great moral or spiritual movement it might, indeed, only exert its highest influence when so allied.

#### *Housing in Scotland*

The association concluded its congress by a debate on the housing programme in Scotland. Dr G V T McMichael, M O H Paisley, opened a discussion on slum clearance and rehousing schemes. He said that, although a great deal was taught and written by medical officers, politicians, and the press on this subject, a great gap existed between precept and practice. The slums still remained a standing reproach. As health officers they were primarily interested, of course, in the problem of the slum from the point of view of its effect on the public health, for the environment of the working classes was the most important of their health problems, and the continued existence of the slums constituted the most serious obstacle to all efforts at improving that environment. The grave insufficiency of fresh air and sunlight, together with the evils—physical, mental, and moral—due to overcrowding, were the special factors in the slum areas. The national exchequer paid large sums of money to provide free treatment for venereal disease, but they still shut their eyes to the overcrowding in slums, which made the practice of morality extremely difficult. Hospitals and asylums were full of victims of alcoholism, which, however, to some extent at least, was due to appalling home conditions. The speaker referred to a rehousing experiment at Paisley, where the local authority provided thirty-four municipal furnished dwellings at rents varying from 8s to 13s 6d per week. Central heating was provided in these by radiators. It was said that money could not be afforded for providing new housing accommodation, but the reply must be that millions of money were already being spent to deal with the end-results of many diseases which were in the main the inevitable outcome of slum environment. The direct material loss in England and Wales due to sickness and disability was estimated at £150,000,000 per annum, and this estimate had never been seriously challenged. There was much grumbling at the present amount of social and industrial unrest, but he asked what thinking persons condemned to live in the sordid atmosphere of the slums could fail to be revolutionaries. Mr A G Dutch spoke on the shortage of housing accommodation for the small-wage earner, and suggested that they leave the higher paid workman, the well-to-do middle class, and owners of businesses to look after their own requirements meantime and erect buildings to meet, to a reasonable extent, the demand of the small-wage earner. He spoke on behalf of the lower paid wage earner who was anxious to work and was able and willing to pay rent and rates with unfailing regularity. He thought the standard of housing should be raised from its lowest to its highest point, not in one effort, but gradually and step by step. Mr Frank A B Preston, in opening a discussion on the effect of the relaxation of building regulations, said that the modifications allowed by the Board of Health had been frequently resisted by local authorities with good purpose. Adequate supervision during building operations would lead to lower maintenance costs, and adequate repair during occupancy would tend to lengthen the period of habitability of houses. Councillor W J Harvey said that the question had been asked whether the housing situation had improved appreciably since the Royal Commission of 1917 had reported. The figures spoke of a methodical and creditable achievement in the last four years, which had been unparalleled in the history of housing. These figures showed that 20 per cent of unsatisfactory houses reported by the Royal Commission were now being dealt with. In Edinburgh 25,000 people would be rehoused within the next year, and at present

1 in every 17 of the population of Edinburgh had better housing conditions as the result of the progress in the last four years. They were entitled, in view of this experience, to say that the slum conditions in Scotland were "on the run." With regard to the provision of houses for lower paid workmen, he thought the solution of the question was an economic one that could be solved when times were better and the worker was able to earn a higher wage.

#### *HARVEY LITTLEJOHN*

The new number of the *Edinburgh Medical Journal* contains a very cordial and knowledgeable tribute by Sir George Newman to the memory of Professor Harvey Littlejohn. He says of him, very truly, that he liked to be what he was, a man of the world in the best sense, happy to meet and co-operate with all sorts and conditions of men—an ambition, it may be observed, more easily to be fulfilled in Edinburgh where most of the members of the learned professions have been boys in the same schools and have attended the same university, than in some larger city. Another characteristic mentioned by Sir George Newman was Harvey Littlejohn's gift of exposition. "There was logic, reason, intellectual grasp, and there was an appealing and persuasive charm for assent. His historical sense and his love of books made him a discerning companion." The final sentence of this charming tribute may be quoted in full.

"Harvey Littlejohn was a good man and a master workman. He was not always easy, not addicted to conventionality, sometimes perverse or inclined to mischief, but a big hearted man, a courageous and dauntless personage, bristling with physical durability with a scroll of high thought and purpose coiled within. He had disappointments, yet he overcame them all. He was not embittered, he was a bachelor yet enjoyed the affections and regard of women, he was witty, a dramatic reciter, vivacious, energetic, but at root kindly, gentle and sympathetic, he was a medical man, yet he had the sense of justice and responsibility of a Judge, he was a Professor but his sociable, unthwarted, he excelled yet was not contented. He was democrat in sympathy and austere in perception. He was both proud and humble. Gay, affable, whimsical, reliable, a man among a thousand, given to hospitality, one who had known great men, a delightful companion, a dear friend. When, far away, he learned he was dead a light seemed to go out and the joy of the world was less."

The same issue of the *Edinburgh Medical Journal* contains the full text of the first Alexander Black Memorial Lecture, which was delivered before the Royal College of Physicians of Edinburgh last June by Dr C F Douglas of Cupar, a member of the Council of the British Medical Association, it dealt with the family doctor as specialist and a fairly full report of it was published in our issue of June 18th (p 1120).

#### *POST-GRADUATE COURSES IN GLASGOW*

The following arrangements have been made for post-graduate teaching in Glasgow during the winter months under the auspices of the Glasgow Post-Graduate Medical Association. Recent advances in medical, surgical, and the various special departments will be dealt with in a series of demonstrations on Wednesday afternoons, from November 2nd to May 30th, the fee for the course is three guineas. Special courses have been arranged in ophthalmology, at the Glasgow Eye Infirmary, and in a slit-lamp course for ophthalmic surgeons in November and December, and a diploma course from January to May. Eight demonstrations on chronic diseases and endocrinology will be given at Stobhill Hospital on Monday and Tuesday afternoons, during the month of February, the fee is one guinea. A limited number of clinical assistantships will be available during the winter months in the various institutions connected with the Post-Graduate Association. Further details may be obtained from the secretary of the association, the University, Glasgow.

#### *TRIBUTE TO THE LATE DR J C McVAIL*

In a preface to his annual report for the year 1926-27 the Stirling County Council and district committee paid a tribute to the late Dr J C McVail, medical officer of health for Stirling. The death of his predecessor, Dr J C McVail, in

one of the first county medical officers appointed consequent upon the passing of the Local Government (Scotland) Act in 1889. Dr. McNeil held that post from 1889, 1891, until the beginning of 1912, when he was appointed deputy chairman of the Scottish National Health Insurance Commission. Dr. Adam writes: "In a word it may be said that Dr. McNeil was one of the chief pioneers of public health. He indeed was a great man, whose interests covered the whole field of public health, and his writings on small-pox and vaccination are quoted as authoritative wherever the subject is discussed."

## England and Wales.

### THE WELSH SCHOOL OF MEDICINE

A CONFERENCE of representatives of the University of Wales and the University College of South Wales and Monmouthshire was held at the College, Cardiff, last week. Both sides were fully represented and the conference was prolonged. It is believed that substantial progress has been made towards a settlement of the question at issue. The decisions, it is said, were unanimous, and will be reported by their representatives to the two bodies concerned.

### RHEUMATIC HEART DISEASE IN CHILDREN

On October 1st a meeting was held at the Bristol General Hospital to consider a scheme which has been in preparation for some time for dealing with cardiac disease due to rheumatism. It was attended by the officers of the school medical services of Bristol, Gloucestershire, Somersetshire, and Wiltshire, including those of county boroughs within the border of these counties and by consulting physicians practising within the same area. The objects of the scheme are research into the conditions under which children contract rheumatic heart disease, and assistance in the treatment of such children. Practitioners within the area have been invited to send brief notes of cases arising among their patients. The scheme is to apply to children between the ages of 5 and 14 years inclusive and is to apply to cases of heart disease arising in connexion with rheumatism, chorea, or scarlet fever, and to cases which though not arising in connexion with rheumatism or chorea are nevertheless rheumatic in type—that is, ventricular enlargement with mitral incompetence with or without aortic incompetence or acute pericarditis.

It is believed that close attention to the problem of diagnosis of the disease in its early stage will be of immediate value to the school medical service. This has been the experience in Bristol, where the plan about to be described has been on trial for several years. It has been found that reference of children with signs suggestive of cardiac rheumatism to hospital physicians interested in the matter has resulted in the removal of restrictions with regard to school attendance, game, drill, etc., in a large number of instances, in others it has been the means of directing children in the early and more tractable phases of the disease into channels of treatment that might otherwise have been missed. The local authorities in the areas named have decided to make arrangements by which children, if the school medical officers think it desirable, may be seen at convenient places by physicians with special experience in the disease. The plan has the support of the Board of Education. The area comprised within these three counties is fortunate not only in having at its centre a city in which work of the kind has already been done, but also in possessing medical officers in all the areas who have already had administrative experience of similar organizations; moreover, they have undertaken to conduct inquiries into the conditions under which the children are living at the time of onset of the disease. Since the district includes wide varieties of soil, altitude, density of population, and so on, information of value should be forthcoming. The investigation, which was initiated by the subcommittee of the Science Committee of the British Medical Association appointed to inquire into rheumatic heart disease in children, has for its focus the University

of Bristol Centre of Cardiac Research. This is based at the Bristol General Hospital, equipped by the University of Bristol, and maintained by several grants. Among these may be mentioned one from the Medical Research Council for clerical expenses, also a Research Fellowship provided for two years by the Colston Research Society, a Bristol organization. To complete the machinery which is being set up, it is hoped to devote a number of beds in the country hospital shortly to be built at Winford, near Bristol, to the treatment of cardiac rheumatism in childhood. The site has been carefully chosen, and is believed to be the best within a convenient distance of the city.

### PRESENTATION TO SIR JOHN ROBERTSON

The conclusion of Sir John Robertson's period of service as medical officer of health for Birmingham was made the opportunity by the staff of the Birmingham Public Health Department to present him with a motor car "as a token of their proud remembrance and good wishes." The Lord Mayor of Birmingham, who presided at the presentation, said that of the many distinguished city officials it was the privilege of Birmingham to employ none was more respected than Sir John Robertson. He hoped that many opportunities would still present themselves for the continued enjoyment of his advice and the social services he had rendered to the city with such satisfaction to all. The Lord Mayor called attention to the great fall in the death rate in the city during Sir John Robertson's term of office. In 1903 it was 16 per 1,000, while at the present time it was only 11 per 1,000—an approximate saving of something like five thousand lives annually. Dr. W. H. Davison, senior assistant medical officer, speaking on behalf of the staff of the Public Health Department, said it was in consequence of Sir John Robertson's sound common sense, his insatiable appetite for work, and genius for administration that such a public health organization had been built up in Birmingham. The Lord Mayor, after making the presentations, handed to Lady Robertson a medallion portrait of her husband as a souvenir of the occasion. Sir John Robertson, in acknowledging the gift, referred to the splendid team work of the staff during his twenty-four years of office.

### QUEEN CHARLOTTE'S HOSPITAL MOTHER SAVING CAMPAIGN

By the kindness of Lady Howard de Walden, a meeting was held at Seaford House, Belgrave Square, on October 6th, in support of the Mother Saving Campaign of Queen Charlotte's Maternity Hospital. This campaign has for its object the raising of a quarter of a million pounds for the erection of new wards at Queen Charlotte's, where an intensive study of puerperal fever and other conditions which lead to maternal mortality may be carried out. The chair was taken by Dr. T. Watts Eden, and there were present a number of mayors of metropolitan boroughs and medical officers of health. Dr. Eden said that between three and four thousand women in England and Wales lost their lives in childbirth every year. The remedy for this grave situation was to have doctors and nurses trained to the utmost degree of efficiency, an adequate and universal ante-natal service, and ample hospital accommodation for all who could not be adequately treated at home. The duty of prevention was equally pressing. In respect of some of the conditions which might attend pregnancy—ectopic, for instance—the task of prevention was comparatively easy, given efficient medical supervision, but, on the other hand, the prevention of puerperal fever was extremely difficult and it was a melancholy fact that during the last fifteen years the mortality from this cause, so far from diminishing, had shown a slight increase. A study of the maternal conditions which bore upon the liability to contract puerperal fever could only be carried out by prolonged and elaborate research. One of the objects of the present appeal was to provide facilities for such research and to bring into closest collaboration the research worker and the bedside physician and surgeon. The Bishop of Wiltshire proposed a resolution pledging the support of the meeting to the campaign and urging the metropolitan authorities to establish committees for the purpose of awakening the public to the importance of the continuing high maternal mortality and the need for collecting funds

for Queen Charlotte's. This was seconded by Dr F E Scrase, chairman of the Metropolitan Branch of the Society of Medical Officers of Health, who stated that that Branch had recently passed a resolution welcoming the campaign. The resolution was supported by Dr T G Stevens, senior consulting obstetric physician of the hospital, who pointed out how difficult it was, now that midwifery had passed so largely into the hands of midwives, for the young doctor to gain sufficient practical experience to do what was required of him when he was called in by a midwife to a difficult case. The mayoress of Paddington and Fulham, Dr Charles Porter, medical officer of health for Marylebone (the borough in which Queen Charlotte's is situated), and others spoke in support of the resolution, which was adopted, and the mayor of Westminster and Mr Alck Bonine proposed and seconded a resolution of thanks to the hostess of the occasion.

#### EXTENSION OF THE GENERAL LYING-IN HOSPITAL, LAMBETH

The General Lying-in Hospital, Lambeth, traces its origin to 1765, when the "New Westminster Lying-in Hospital" was founded, largely owing to the efforts of Dr John Leake, a lecturer in midwifery. This institution, which was situated near the south end of Westminster Bridge, was completed in 1767. In 1824 the present site in York Road was obtained, new buildings were erected, and were taken into use in September, 1828. It is interesting to recall that in March, 1879, Lister became consulting surgeon, and his connexion with the hospital continued in this capacity and as president until 1911. Moreover, in 1880 the late Sir John Williams and the present president, Sir Francis Champneys, were appointed physician-in-concubitus to the hospital, and under their auspices antiseptic midwifery was introduced. In 1879 the systematic training of midwives was begun and grew eventually into the present training school. In 1907 two houses adjacent to the hospital were included in a new lease, under the terms of which rebuilding was ordered before the end of 1930. These premises were at first used as a nurses' home and subsequently for an ante-natal clinic and infant welfare centre, a clinic for mothers, they also accommodated some of the nursing staff and pupils. An appeal has now been issued for £30,000 for rebuilding. The proposed extension will cost some £40,000, towards which about £10,000 has already been given or promised. It is hoped that greatly improved accommodation for the nursing staff and pupils will thus be obtained, and better facilities created for out-patients and for teaching. This is the first public appeal for funds by the hospital since June, 1765. Subscriptions should be sent to the honorary treasurer, Dr J S Furburn, at the hospital.

## Ireland.

### TUBERCULOSIS MEDICAL ASSOCIATION Milk Infection

At the annual meeting of the Tuberculosis Medical Association, held recently in University College, Dublin, when Dr M J Cuffe presided, Dr Boyd Barrett of the Local Government and Public Health Department read a paper on infected milk, in the course of which he said that since it was clear beyond doubt that bovine tuberculosis was prevalent and was the cause not only of disease, but of death in man, there were two problems to be solved: (1) Bovine tuberculosis must, if possible, be eradicated, and (2) the infection of human beings by milk must be prevented. The ideal solution of this problem would be the establishment of herds of non-tuberculous cattle, and all measures now tried should have that ultimate object, and facilities for the bacteriological examination of milk should be provided. The powers available for the examination of milk for dilution and fat deficiency should be in some way applicable to the test for tuberculous infection. He suggested the application of the Swedish law which made it imperative that persons working in dairies or concerned with the sale of milk should be in possession of a medical certificate delivered less than a year before the time of their engagement,

stating that they were not suffering from contagious tuberculosis, with severe penalties and stoppage of sale of milk for non-compliance. Every dairy farm and dairy should be registered, and registration should be followed by inspection by a veterinary surgeon, so that all diseased animals might be discovered. In this way the chance of advanced cases of tuberculosis could be begun, leading eventually to the separation of healthy from tuberculous reacting cows. Thus also a basis would be laid for attaining the ultimate object of the rearing of tuberculous free herds. The next step would be the testing by tuberculin of the remainder of the herd and then the milk of cows giving the reaction of tuberculosis should be tested for the presence of tubercle bacilli. This investigation should be followed by the pasteurization of all milk intended for public consumption which had been found to be infected. In general about 10 per cent of milk, milk contained tubercle bacilli. The percentage varied in different countries, and it had been found that 8 per cent of Dublin milk was infected.

#### Costs of Tuberculosis

Dr Patrick J Burke, tuberculosis medical officer for county Sligo, read a paper on the costs of tuberculosis directed to answering the criticism that the tuberculosis schemes in the Irish Free State were expensive without giving any returns. Since the establishment of the schemes there had been a great decrease in the number of deaths from tuberculosis. In 1915 there were, in the present area of the Free State, 6,723 deaths from tuberculosis, while in 1925 there were 4,675, a decrease of 2,052. He quoted various estimates of the value of each life lost to the nation by tuberculosis. The lowest estimate he could find was £500, but to remove any suspicion of exaggeration he would take as a basis £300. Taking with Sir George Newman, the average duration of illness prior to death from tuberculosis is three years, with loss of wages at £20 a year, and cost of sickness at £100 a year, the cost of disability in each case would be £360, making with the loss by death a total of £660. The reduction of death in the Free State in 1925 as compared with 1915 meant a saving for that year of £1,354,320. On the other hand the annual loss to the country by disease and death due to tuberculosis could be calculated at £4,347,272, while the present expenditure on county schemes was about £75,000 a year. Dr Burke claimed that although his figures might look extravagant, they were based on calculations made by responsible statisticians, his part being only to apply them to the conditions of the Irish Free State. Dr J McMahon, a well known New York authority, delivered a lecture, illustrated by lantern slides, on tuberculosis treatment in America.

## Correspondence.

### CATARRHAL VACCINES

SIR,—A letter was published in your issue of June 4th 1927 (p. 1033), from Dr N A Spott, giving some statistics of the incidence of influenza in inoculated and un inoculated boys at St John's College.

The figures in that letter refer to three houses only, and since they may create a somewhat partial impression of the results of inoculation in that school, the figures for all houses, including those already mentioned, are given below.

The inoculations were carried out during the autumn of 1926, mostly in the latter part of September and the first half of October, "antitubercular" vaccine of St Mary's Hospital being employed in most cases. A few boys had autogenous vaccines, and a few had stock vaccine. All the St Mary's "antitubercular", 227 boys received three injections at weekly intervals, the doses varying with the age and size of the boy, 28 had only two injections and 14 had only one. 16 others had from twelve to fifteen injections each.

In January, 1927 immediately after the school recess a widespread epidemic broke out, and the incidence of disease amongst the inoculated and un inoculated is given in the accompanying table.

The epidemic was of a mild type, and complications were few. There were no cases of pneumonia. One boy had bilateral otitis media which extended to the mastoid cells, and necessitated surgical treatment on both sides. Two others had extensive bronchitis, which necessitated prolonged sick leave. One boy got better and relapsed several times. All the patients had been inoculated. Two boys who had not been inoculated had otitis media, from which they recovered after paracentesis.

It would have needed more clerical work than was possible to estimate with accuracy the number of school days lost by inoculated and uninoculated boys respectively.

The table shows that there was very little difference in the incidence of the disease in the inoculated and uninoculated groups. It is apparent that the percentage of boys attacked is greater in the inoculated than in the uninoculated group, but this may be accounted for by the fact that the inoculated group contains most of those boys who are particularly subject to influenza and other catarrhal infections.

It is interesting to compare the figures in the table with those collected from another school, and published in the Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1926 (p. 64).

Out of a total of 47 boys 144 (32 per cent) were inoculated and of the 54 (33 per cent) were attacked 333 boys were not inoculated and of the 109 (36 per cent) were attacked. The attack rate for inoculated boys and for uninoculated boys was therefore practically equal. The results seem to show that no protection against influenza was afforded. On the other hand all the fifteen cases of pneumonia occurred in boys who had not been inoculated (one case uncertain) so that it appears that inoculation may have had some protective value against this serious complication.

Table showing Attack with Reference to Inoculation

House	No of Boys	Boys Inoculated		Boys not Inoculated		All Boys To all not attacked
		No	Not attacked	No	Not attacked	
1	43	9	3	31	7	19

### CONVULSIONS DURING ANAESTHESIA

SIR—I have read with interest the reports of cases of convulsions during anaesthesia which have appeared in the JOURNAL and have been struck by the fact that all of them, except those reported by Dr Hornabrook (September 10th) and attributed by him to overdose of atropine, have occurred where ether was administered by the bomb method. Dr Pinson (May 28th) reports fifteen cases, eleven or which occurred in his own practice, giving an incidence of 1 in 1000 and four other cases, and Dr Dickson (October 1st) reports one case. Dr Sington, in his letter

of September 24th, disposes of the theory that atropine is the cause.

It would be interesting to hear from other anaesthetists if they have experienced this complication when administering ether by other methods. Personally I have never seen it, and venture to suggest that the bomb is the source of the trouble—whether, as Dr Dickson hints, due to a high concentration of ether or an excess of carbon dioxide, or, as I think, to something inherent in the superheating of the ether which the bomb method involves.

My own experience of the bomb extended over some two hundred cases, and, although no convulsions occurred, I was led to give it up because of the higher proportion of respiratory complications which followed than when ether was given by one of the ordinary open methods. Possibly the cause of this, as well as of convulsions, is to be sought for in the action of relatively high temperatures on ether vapour. It seems to me that there is a field here for chemical research—I am, etc.,

Glasgow Oct. 4th.

H. P. FAIRLIE, M.D.

SIR,—In the discussion upon convulsions during ether anaesthesia two correspondents have suggested that the cause is an excess of carbon dioxide. This appears to be an untenable hypothesis for two reasons. In the first place, other spasm has occurred during endotracheal ether anaesthesia, where the carbon dioxide content in the alveoli is less than normal. Secondly, several cases of severe ether spasm have been treated by the inhalation of a mixture of 90 per cent oxygen and 10 per cent carbon dioxide. This treatment appears to be the most efficient at present known in restoring regular deep respiration—I am, etc.,

C. LINGTON HEWER, M.B., B.S. Lond.

London N.W.1 Oct. 6th.

### ACTINOTHERAPY IN JOINT TUBERCULOSIS IN CHILDHOOD

SIR,—The results mentioned in the memorandum of Dr Crosbie and Aidin in the BRITISH MEDICAL JOURNAL of October 1st (p. 594) are so unusual that it would perhaps be instructive to compare them with those obtained at the Finsen Institute, Copenhagen.

Site of Tuberculosis	Improved		No Change		Made Worse	
	Alder Hey	Finsen Institute	Alder Hey	Finsen Institute	Alder Hey	Finsen Institute
Knee	100%	79%	—	20%	—	2% (died)
Hip	15%	68%	45%	26%	33%	5% (died)
Spine	57%	74%	—	13%	43%	13% (died)

\*Two cases only.

The Finsen Institute figures are also classified as follows

Site of Tuberculosis	Cases Cured				Cases Improved
	Total	Free Movement	Partial Movement	Without Movement	
Knee	71%	31%	15%	2%	8%
Hip	64%	5%	26%	37%	—
Spine	60%	60%	—	—	9%

The Finsen Institute results are based on fourteen years' experience and the 6 from Alder Hey on just over one and a half years.

In the cases from Alder Hey no mention is made of the duration of the course of treatment, and it is fair to infer that it is unlikely that all the cases commenced treatment at the same time. This would mean that conclusions, in some cases, were arrived at after (for tuberculosis) a comparatively short period of treatment.

I would also suggest that the writers are mistaken when they state that they have used at Alder Hey an open arc with an arc voltage of 250 volts.

Dr Crosbie and Aidin state that they are convinced that

actinotherapy is of little or no value in the treatment of tuberculosis of the knee, hip, and spine, and that in some cases it appeared to be injurious.

I would suggest that this opinion is unwarranted, especially when the Alder Hey results are compared with those from the Finsen Institute—I am, etc.,

Newcastle on Tyne Oct 1st

W KERR RUSSELL, M D

SIR,—We feel that the memorandum by Drs Croshaw and Aldin on "Actinotherapy in joint tuberculosis in childhood," published on October 1st (p 594), cannot be allowed to pass unchallenged.

It would appear that the conclusion reached—namely, "we are convinced that actinotherapy is of little or no value in the treatment of this form of tuberculosis"—is somewhat hasty, considering that the total number of cases under review was only 45. The figures quoted show that, as a result of treatment with or without light, 33 per cent of all cases did not benefit, the statistics of this hospital show that, out of 785 cases treated between the years 1914 and 1924 and manifesting similar lesions, all but 14 per cent responded satisfactorily to treatment without actinotherapy. Subsequent to this date actinotherapy was introduced, and the response to this adjuvant method has been observed, and will be recorded in detail in the future.

Whilst it is admitted that there are certain cases (notably those complicated by sinus formation and secondary infection) which do not benefit by light treatment and no more worse thereby, the response observed in uncomplicated cases of tuberculous joint lesions has been such as to justify the continuance of its use.

In conclusion, it must be added that the type of case to which the memorandum refers is treated in this hospital by immobilization on similar splints to those mentioned, and it has not been found that frequent lifting and transport in any way produces minor degrees of trauma, nor does it militate against the success of the fixation for which these splints were specially devised.—We are, etc.,

#### "THE HISTORICAL ASPECT OF QUACKERY"

SIR,—After reading Professor A J Clark's address under the above title, I have come to the conclusion that it might be well if he would follow the example, so far as in him lies, of some of his predecessors, and try to make history, as he seems utterly incapable of accurately recording a historical fact.

He says, "The term quack simply means one who pretends to knowledge or skill that he does not possess." With such a definition I do not quarrel, as it certainly includes a large number of professors and leaders in the orthodox medical profession. It would seem to me that in this country there are more qualified than unqualified quacks, though possibly, from what Professor Clark tells us, the reverse may be the case in Germany. Albert Abrams, who is Professor Clark's *bête noire*, said that "there is no harm in being called a quack, the mischief is in being one." A statement worthy of the thoughtful consideration of everyone who assumes the role of teacher.

Professor Clark says "The question that I wish to consider is why the general public so often turns away from the medical profession and follows quacks who pretend to the possession of cures unknown to medical science." He miserably fails to give a satisfactory answer to his own question, but I shall try to do so for him. The fact is undoubted, and is frankly acknowledged by Professor Clark, that the public is drifting away from orthodox practitioners. It is much better to face the true facts and try and remedy them rather than rest content with Professor Clark's palliative, "that, although the alliance [of the medical profession] with science has brought them great material success, yet it has brought its special penalty in that it is ever alienating them to an increasing degree from the fundamental beliefs of the common man."

Who enjoys the *great material success* in the form of the current coin of the realm?—certainly not the general

practitioners, for whom this special dose of soothing syrup is prepared. The plain and obvious facts are that the general practitioners in the present day are imperfectly taught by many quack professors who neither know how to prevent or cure disease. In an address at Montreal in 1911, on Preventive Medicine, I said that there was not a Medical School in the British Empire where Preventive Medicine was taught as it should be taught, and I say so still. No teacher or medical head professes to cure disease, he only draws the fees, while watching Nature do the job. If you look over the *Quarterly Journal of Medicine*, you rarely find more than a few lines on treatment. No wonder, then, that general practitioners often fail to deliver the goods, and allow the quacks to romp in. Almost universally the orthodox practitioner has the first innings, and he ought to be ashamed of himself when he is woisted by the quack.

Professor Clark talks largely about Medical Science, but where is it? There is a large amount of scientific work going on in physics, engineering, radiation, aviation, bacteriology, and physiology, but pharmacology and clinical medicine have not yet touched the fringe of science. The treatment of disease is not a science, nor a refined art, but it is a thriving industry. The pharmacologist has usually got a whole-time job and he may know something about a rabbit or the very rapid beats of the heart of a canary, but the only treatment he has got for fibrillation of the human heart is poisonous doses of digitalis and quinine.

Sir Arbuthnot Lane once said, what I have often said in more forcible language, that surgeons make their living out of the ignorance and utter incompetence of physicians, while Sir Almroth Wright thinks that in 200 years the chemist may have acquired such a knowledge of his subject as to be able to prognosticate with some slight degree of accuracy. Albert Abrams said that our advance in medicine which is not in conformity with physical science is doomed to perdition. This is the man whom Professor Clark links up with a certain Eliza Perkins. I know very little about Perkins, except what Professor Clark has told us on more than one occasion, but his version seems to vary very considerably. On the 1st occasion, Perkins's instruments or tractors were made of wood, and sold at £10. Now this marvellous Perkins "persuaded millions that all disease could be cured by stroking the body with two pencils of metal." If he ever sold two million pencils at £10 the pair, he would be a very wealthy man, even Harley Street would not be in it with him. I should like to devote a whole chapter to this wonderful persuasive individual, but I must pass on to Albert Abrams, about whom and his work I know a great deal.

The men who are carrying out Abrams's method of diagnosis and treatment are qualified medical men and therefore if they be quacks, they are quacks within the fold. I happen to know a good many of them, and I can truthfully say that every one I know is as honest as Professor Clark, and not one of them charges extortionate fees—in fact, they have often to go without fee, as many of their patients have parted with almost their last shilling before coming as a *dernier resort*. Are the following practitioners of Abrams's methods quacks? Proctor Hall of Vancouver, of whom I stated that he combines in his own person the qualities of the physician with those of the scientific physicist, and I may add, from my personal appreciation, those of the Christian philanthropist. Dr M C Hardin of Atlanta, Dr Francis Cave of Boston, Dr Jules Regnault of Toulon, ex-Professor d'Anatomie at l'Ecole de Médecine, author of *Les Méthodes d'Abraham*, Dr H Verploegh of the Hague. For obvious reasons I do not mention the names of any who are practising Abrams's method in this country, as, one and all, they obey the advertising—they allow their work to advertise them.

I have often said that Abrams is the greatest genius that medicine has produced during the last half-century, and I say so still. Take every really great man who has had his intellectual followers who were outnumbered by the virulent infuperators of the *American Medical Association*, who saw their craft in danger. There were his exponents or camp followers who thought that in an easy way of making money. These latter have followed that Abrams's methods were a difficult path to tr

they have all gone back to their Matera Medea. On more than one occasion I told Abrams that he stood in greater danger from his friends than his enemies, as the latter could be easily refuted, *Magna est veritas, et prevalebit*, but the public were apt to judge a man by the character of his followers. I believed Dr. Francis Cave and others spoke to him in similar terms.

I have often said that if Abrams had done nothing more than discover the cardiac and pulmonary reflexes, he was entitled to a prominent niche in the temple of fame. I also say that the man who does not know the whole of Abrams's spinal reflexes is badly handicapped in the practice of his profession. This almost universal ignorance often enables the osteopath to score over legally qualified medical men. In this city a well known artist who regularly exhibits in the Royal Academy was under the care of highly qualified medical men for six months with "neuritis of right arm." The loss of the use of the right hand stopped her work, and as she could not afford to be out of action any longer, she went to an osteopath, who put her right in three weeks. Such reasons for the public drifting to "quacks" could be multiplied almost ad infinitum.

It puzzles me that Abrams's critics always jump at his last work, about which they know nothing, and never read his monumental work on spondylotherapy, which might come within their comprehension. Professor Clark tells us that "the followers of Abrams believe that all diseases can be both diagnosed and treated by means of two boxes containing some simple electrical apparatus." The pharmacologist deals in simples, but this will be news to Abrams's followers. Abrams's diagnostic apparatus does not contain any electricity, unless such as is supplied by the magnetic currents of the earth, and that in the body of the subject under examination. The oscilloclast is a broadcasting machine though it could not carry Professor Clark's address to say, the *Irish Times*, in which it appeared. With a pair of earphones, having a resistance of 2,000 ohms you can hear the electro-magnetic impulses singing through all parts of the patient's body. Moreover I have often tuned my wireless set to receive and deliver these vibrations through the loud speaker after they have travelled more than 200 feet and passed through a thick brick wall in order to reach the aerial.

In Dr. Brunori's new instrument if a small lamp is moved close to the treatment lead, it lights up at the crest of the wave and in this way you can easily discover the length of the wave.

A statement by Herbert Spencer I can commend to Professor Clark and company, though I can scarcely hope that they will profit thereby. "There is a principle which is a bar against all information, which is proof against all argument and which cannot fail to keep a man in everlasting ignorance. That principle is condemnation before investigation."

I am amazed and amused at Professor Clark's confession of faith in Sir James Frazer's twaddle about magic. According to this authority, it would seem that two existing races of mankind, while differing in religious beliefs, are united, not by a belief in a Supreme Being but by "a solid statement of intellectual agreement among the dull, the weak, the ignorant, the vast majority of mankind." This universal faith, this truly catholic creed, is a belief in the efficacy of magic. It would seem, according to Professor Clark, that "in a civilized community the belief in magic is concealed beneath the veneer of education and does not obtrude itself in normal life, but the veneer cracks as soon as any strong emotion is aroused, and both pain and fear of death are potent causes for arousing such emotions." It would appear that it is not the fear of God or of the devil that makes people anxious to live, but merely the love of life. So when the veneer, which of course, is of various thicknesses, is cracked, the solid substratum of the belief in magic oozes out, and then all savage and civilized man, rich or better shelter in search of a magician, every one seeks out a different magician, according to his taste. Those who rush off to the Abrams Cult would seem to be the more intelligent with the thickest coat of veneer and I hope, unlike the savage, are not naked, but clothed and in their right mind.

The Abrams practitioners should be very pleased that they are reckoned among the Magi, but they must recognize that when literary men in the front rank, judges, barristers, members of Parliament, clergymen, and even medical men, come for their "magic box," they all have had their veneer cracked, otherwise they would have gone down to perdition like sensible men, under the care of an orthodox professor.

I most unhesitatingly say that if anyone gave such evidence of his belief, as is portrayed by Sir James Frazer and Professor Clark without a shadow of proof, in any court of law in the world, he would not only be laughed out of court, but be rightly adjudged a greater fool than he looked. I presume Professor Clark would assume that Comm. Doyle was suffering from a delusion when he heard Abrams's oscillophone regularly hiss whenever a piece of cancer tissue was brought near it. Many of us think that it is a melancholy calamity that Abrams was virtually killed by his enemies before he had perfected that instrument.

Abrams's work has progressed more rapidly and more widely since his death than it did in his lifetime. In the large Central Hospital of Philadelphia, which is a general medical and surgical hospital with special departments, one floor has been specially installed for Abrams's work. The literature is rapidly increasing: there is a monthly journal. In addition to the work now in the second edition, which I had the pleasure of editing, there is one in Spanish, one in French, by Dr. Jules Regnault, and in my opinion the best of all is a large volume in Italian by Dr. Brunori. The feeble bleat of a professor is not likely to arrest the progress of this great work for a second—I am, etc.,

JAMES BARR

London O. 2nd.

SIR,—Although in your leading article on quackery (October 1st, p. 603) you clearly distinguish between the quack and the qualified practitioner, I am disappointed that you allow Professor Clark to ignore the distinction without specifically pointing out his error. I can scarcely think that this means that you tacitly approve of an attitude which, however atractive to the ultra-orthodox, is logically indefensible. But I should like to have your assurance on this point.

From Professor Clark's analysis of quackery it obviously emerges that a quack may be fully qualified in medicine and surgery. It is only necessary for a qualified practitioner to be a homoeopathist or follower of Abrams—"that is to say for his theories and practice to seem absurd in orthodox eyes—for him to be a quack."

What, then, is the significance of "qualification"? The idea that it implies the possession of sufficient knowledge and skill by an individual to justify his using his own discretion in the conduct of medical practice must be erroneous. The official regulations which recognize professional freedom must be all wrong.

Is this indeed the authoritative point of view? If it is, does it not give quackery great power, for according to it there must be hundreds of professional men and women (even in the British Medical Association) to whom the opprobrious term may be applied? Then again, if it is, how shall we all agree as to the permanent criterion of quackery, and which of us shall judge the rest?

I beg to differ from Professor Clark and suggest that a quack cannot usefully be defined as "simply one who pretends to knowledge or skill which he does not possess" without reference to medical qualification, because not only is proof of such pretence practically impossible to obtain, but the question as to who is to be authorized to convict anyone of the pretence is insoluble save by reference to some sort of "qualification."

"Quack," in my opinion, can only be the term applied by a body of people, qualified for healing work in a certain way, to others who attempt healing without this special qualification which they (the qualified) consider essential.

In order to illustrate how impossible Professor Clark's position becomes, I may remind him that he admits that such methods as that of Abrams may produce results but only through a psychic process, thereby clearly showing that he has no suspicion that any "followers of Abrams" may agree with him on this broad issue for he could hardly condemn them as quacks if he thought they agreed with him.

Thus is afforded excellent proof of his imperfect knowledge of the theories of certain doctors whom he calls "quacks." Personally I use Abrams's method and believe in the psychic rationale of the system, although my conception of this rationale is probably widely different from that of Professor Clark. So possibly I am in favour. But what of those who do not explain the Abrams phenomena on a psychic hypothesis? There should be no difficulty for Professor Clark. He has illustrated very well his capacity for judging without obtaining full evidence in one instance. What is to prevent his doing so again? From his sweeping statement about the extravagances of the "followers of Abrams," it appears that he has not even cursorily read the only book on Abrams written by British doctors (*Abrams' Methods of Diagnosis and Treatment*, published by Hahnemann), for the writers of this book do not commit themselves to any special theory and are careful to repudiate all fantastic claims—I am, etc.,

London W 1, Oct 3rd

J KENILM REID

SIR,—In the article with the above title in the JOURNAL of October 1st appears the following sentence

The career of Hahnemann, however, is a striking example of the way in which a rebel against authority who commences with an appeal to reason may finish by establishing a dogmatic faith even more absurd than the orthodox traditions he tried to explode.

I presume that Professor Clark, the author of the article, is not here referring to Hahnemann's teachings concerning dietetics, personal and municipal hygiene, the management of epidemics, or the treatment of the insane, as these teachings, revolutionary as they were in his time, are now accepted by the profession as a whole, although the part which he played is conveniently forgotten.

Professor Clark is evidently referring to the principle of similars, and in referring to it in such terms he is himself filling the definition of a quack, which he postulates at the commencement of his article—that is, one who pretends to knowledge which he does not possess.

Hahnemann's first publication on the principle of similars followed twenty years' careful experimentation. He stressed over and over again the need for experiment, and repeated experiment. Surely in these scientific days it might be expected that those who attempt to refute his findings would base their refutation also on experiment.

Those who, like myself, are experimenting daily with ample clinical material, and accept the principle of similars as a working basis in prescribing, do not "challenge the findings of experimental science." On the contrary, we welcome them, but we cannot discover anything in those findings which contravenes in the least the principle by which we are guided. Rather, indeed, is the converse true.

Finally, Sir, might one be permitted to point out that at no time, either in your JOURNAL or in any other medical publication, has there appeared a scientific refutation of homeopathy. You have steadfastly refused to print anything which has the appearance of supporting it, whilst you have admitted to your pages scathing references which are totally unsupported by any scientific evidence. Those who accept the principle make their appeal to experiment. If it is refutable, let it be so refuted. To act otherwise is to be guilty of intellectual dishonesty.

I dare to hope that you will have the fairness to print this letter—I am, etc.,

Liverpool, Oct 1st

#### DEATH CERTIFICATION

SIR,—The Births and Deaths Registration Act of 1926 has been in force now since July 1st, and most of us in practice have had to fill in one of the new death certificates. Apart from having to fill in two certificates now instead of one as before, we have to watch our step warily in case we cross out the wrong "did not" or "was held."

This I mention as a locumtenent of mine, in excess of professional zeal, crossed out the wrong "not," indicating thereby that a post mortem examination was held. The result was the return of "informant," greatly agitated, from the registrar's, the hasty scribbling of a "private" certificate refuting the suggestion, and much grumbling all round. Again, the certificate was duly posted, but not delivered in time to the registrar, and this led to telephone

messages from the exasperated friends. The result, I am informed, is that I may hand the certificate, finally sent to the friends, as the Postmaster-General's efforts at this position locally are unsatisfactory.

The details of cause of death are supposed to be very private and confidential, yet the friends may obtain a copy of the certificate from the registrar for one shilling or have I left out the sixpence?

Again, when filling in cause of death we are advised to think backwards, but the end-result does not appear to differ materially from the "primary" and "secondary" of the old certificate.

Providence knows we are harassed enough with certificates of various kinds, but this latest outgrowth on the official tree of 1910 and refreshing fruit makes one long for a hatchet—I am, etc.,

VINCENT P NORMAN, M D, F R C S D

Bradford, Sept 27th

#### MOBILE LABORATORIES IN THE WAR

SIR,—In your issue of October 8th (p. 660) Sir Robert Porter writes that certain statements made in the obituary notice of Adrian Stokes which you published the previous week "have no historical basis as to fact." I had not the privilege of knowing Stokes before he came to Gm's, so I had to depend upon information gained from various sources for what I wrote about his services, and particularly from Dr J A Ryle, who lived in the same house with him for more than two years, both before and during his services with the Second Army. I naturally took every precaution that the information should be trustworthy, and further investigation convinces me that my statement is accurate in every detail. There is no doubt that Stokes, through his own enterprise and initiative, discovered the typhoid carrier in the Grenadier Brigade in 1914, thereby anticipating the functions of a mobile laboratory, which was not apparently then available to do the work. It was not implied that Stokes instigated the creation of mobile laboratories, but merely that he anticipated the idea. It was nowhere suggested, as Sir Robert Porter seems to think, that Stokes's work in the Belgian epidemic was done during service with the Second Army. Dr J A Ryle, who worked intimately with him at the hospital at Malpassé near St Omor, to which some 800 Belgian civilian cases of typhoid fever were evacuated, tells me how he witnessed from day to day the ready enthusiasm with which Stokes co-operated with the officers of the Friends' Ambulance Unit and the sanitary officer of the Second Army, and the thoroughness with which he and his colleague, the late Cecil Clarke, worked in their laboratory to ensure that no civilian carriers should be returned to the occupied areas to cause further damage to the troops. For these reasons the remarks concerning Stokes's participation in this not unimportant episode of the war are fully justified. As Dr Ryle has said, Stokes acted as "an unofficial liaison officer," for at this period as well as later at the casualty clearing station, although employed in a specialist capacity, he was continually consulting all those with whom he came in contact, whether civilian or military, in their joint task of helping to protect the British forces from infectious disease. The hospital at Malpassé was not under the medical control of the Second Army, but it played a very important part in dealing with the typhoid epidemic amongst the civilian population in the early months of 1915, and no history of the epidemic would be complete if it omitted to record the invaluable services of the bacteriologists at that time.

—I am, etc.,

(Writer of the obituary)

#### THE TESTING OF DISINFECTANT

SIR,—Referring to our letter dated September 27th (p. 614) we much regret that we omitted to state that we were not the originators of the Rideal-Walker test as stated in our letter of July 9th last (p. 79), which was originated by Dr Samuel Rideal, the father of us, and Mr J T Ansie Walker, to whom we tender our sincere apologies, and much regret our mistake.

## Obituary

### HENRY EDWARD ARMSTRONG D.H.,

Formerly M.O.H., Newcastle-on-Tyne

On October 5th there passed away Dr Henry Edward Armstrong the first medical officer of health for Newcastle-on-Tyne. He came of old seaman stock and was born in 18-3, at Chipchase Mill in the beautiful North Pine Valley. On leaving Brampton School he served his apprenticeship at the Newcastle Dispensary, studied at the Newcastle College of Medicine (Neville Hall), and took the diploma of M.P.C.S. in 1864, and that of L.S.A. in 1867.

His first appointments were as resident medical officer to the old Newcastle Dispensary, City Road, and medical officer to the old fever house, the centre of the provincial fever hospital (1867). In 1875 the city council of Newcastle-on-Tyne resolved to appoint its first and whole-time, medical officer of health and after much formal calling upon electors, and interviewing candidates, Armstrong was selected. He held office until the end of 1912, when he retired on pension.

Armstrong's life history is inseparably associated with the rise of sanitation in England and he was the intimate friend of such men as Buchanan, Thorne Thorne, Power and Murphy.

In spite of intense prejudice and frequent opposition at first, Armstrong ultimately carried his council with him. When he first took it in hand Newcastle was an ancient city clinging desperately to the past centuries in its narrow stifling courts and acres of crumbling tenements and its citizens held most of the prejudices which are to-day regarded as the merest essentials of healthful living. It is due to Armstrong's persistence that practically all the old noxious areas are now swept away, and that Newcastle, although it has an acute housing problem of its own, has to-day singularly few slums.

Armstrong was well in advance of his time, and it is only now ready to grace at his early reports to receive something of a shock on finding many of the newest ideas of to-day advocated by him (and probably laughed at) forty years ago. In 1882 Newcastle obtained powers which anticipated some of the most useful sections of the Public Health Acts Amendment Act, 1907—for example that empowering the local sanitary authority to deal directly with condemned property, instead of having to refer to the magistrates.

Armstrong was one of the earliest and keenest pioneers in the campaign against bovine tuberculosis in meat and milk, and as far back as 1892 Newcastle obtained powers limited it is true to deal with tuberculous milk. It was for many years his practice to condemn and seize the whole carcass of a food animal in which any visible evidence of tuberculosis appeared on the ground that "there is no such thing as 'localized' tuberculosis, but that the disease germs must reach the sites of the various vulnerable lesions through the circulation—a theory that has since been proved correct. He drafted a bill long before John Burns's Milk and Dairies Bill, that anticipated the essential principles of the latter, and went even further, but it was considered so drastic at that time that no one dared take it up.

In connexion with epidemiology Armstrong was among the first to study the influence of the tramp in the spread of disease and his reports on small pox and varicella in 1893 and 1904 provided much new information which had been laboriously collected. The City Hospital for Infectious Diseases was opened in 1888 and has served as a model for many fever hospital elsewhere. In it a proper service of nurses was substituted for the attendants in the old fever house whose sole qualifications for appointment were that they should have had "the trophies" and that they

Dr Armstrong was medical officer of health to the Tyne Port Sanitary Authority from 1881 till 1896. He made various contributions to the literature of marine hygiene, the need for which is hardly to be said to have been recognized in those days. His resignation was due to difficulties created for him by strong local interest as the result of his bold denunciation of the conditions on many ships sailing out of the Tyne. He was unbending in his honesty and had the courage of his convictions, to which he adhered with tireless tenacity.

With the late Dr H. J. Yeld of Sunderland Dr Armstrong was responsible for the founding of the Northern Counties Association of Medical Officers of Health in 1875. This died or merged in 1882, in spite of the efforts of its energetic secretary. He was twice president of the Society of Medical Officers of Health—in 1889 and 1890—and from 1891 till 1893 was president of its Northern Branch which met in his office for over thirty years. After the reconstitution of the society he was elected an Honorary Fellow in 1920. He was also a corresponding member of a number of foreign medical societies. Dr Armstrong was a member of the British Medical Association, and at the Annual Meeting at Newcastle-on-Tyne in 1893 he was president of the Section of Public Medicine and opened a discussion on cholera.

Dr Armstrong was intimately associated with the University of Durham College of Medicine from 1878 to 1887, he was its honorary secretary and was subsequently a governor. He was lecturer on botany from 1873 till 1877, and on hygiene and infectious diseases, from 1877 till 1912. He had high ambitions for the College and was chiefly instrumental in bringing it about that the University of Durham was the first to grant a degree in hygiene. He himself was the first recipient of the D.H. conferred on him, *honoris causa*, in 1891.

Armstrong had a strong literary taste, and was a scholarly and widely read man himself a purist in style, a piece of scholarly composition in the report of a subordinate would cause him acute irritation. He was melodious and precise in his work, and insisted upon absolute accuracy and punctiliousness in all office affairs. He dabbled in music and art, was a keen photographer, an enthusiastic angler and a well-travelled man. At the age of 65 he took up roller skating

and spent much of his spare time for some years subsequently in that vigorous pastime. He was an excellent raconteur, with a strong sense of humour, and there never was a more delightful host. He was hard-working, energetic, and impulsive and a fair dealer. He was loyal to his friend and kindly and condescending to those under him. He had the warm affection of his staff, and his was always a happy department no matter what troubles assailed it from without.

We who knew him only in his later years are perhaps a little apt now to forget his active and successful career, so short is our memory of men once they drop out of their accustomed place. But he who has just gone to his long rest was by no means the least of the stalwart pioneers of the latter half of last century who by their patience and tenacity gained so much that has made life more comfortable and more secure for us and for succeeding generations.

H. K.

### Sir THOMAS OLIVER WRITES

By the death of Dr Henry Armstrong the last link in the chain of a particular generation of teachers in the College of Medicine has been severed. Petting from the post of medical officer of health for the city in 1912—an appointment which he had held for thirty-nine years—he found great pleasure in the books of his well-chosen library and by remaining in touch with the hygiene problems of the times, largely through the friendly association which existed between himself and Professor Kerr, who succeeded him in

H. E. ARMSTRONG  
(Portrait by James Watson and Sons  
of Newcastle-on-Tyne)

the health appointment of the city. A few years ago it was apparent that the physical changes incidental to advancing years were making silent encroachments upon his frame and were limiting his capability for outdoor exercise. He thus gradually fell out of the ranks, but he always had a warm welcome for any friend who went to see him. By this means his interest in passing events was kept alive.

Before his appointment as lecturer on public health in the College of Medicine, Armstrong for a few years discharged the duties of the chair of botany. When I became connected with the College of Medicine at the close of the late seventies there were on its council George Yeoman Heath, Philipson, Gibb, Arnison, Page, Gibson, McBean, Luke Armstrong, and Henry Armstrong, and there had just been introduced into the College men of a younger generation—Purmond, Murphy, and Meais.

At the College of Medicine was adjacent to the Mining Institute in Orchard Street, and its secretarial duties had been entrusted to Dr. Henry Armstrong, who was scrupulously careful in recording the minutes of the meetings and conducting the special affairs of the College. When in 1873 he became medical officer of health for Newcastle-on-Tyne the public health movement had only recently taken shape, and he felt that a large field of usefulness lay in front of him, and that it could only be tackled by an all-time appointment. His residential position at the dispensary, and that of visiting physician to the Fever Hospital, gave him opportunities, not only of seeing and treating the various types of epidemic disease, but of studying disease generally. On relinquishing the dispensary appointment he became medical officer of health to the River Tyne Port Sanitary Authority, and a few months afterwards was made medical officer of health for the city. At that date typhus fever was not an uncommon endemic in our large seaport towns, and to this as it affected Tyne-side Armstrong devoted considerable attention. Armstrong was painstaking in the preparation of his annual reports, he was a stickler for accuracy and persistent in his opinions, which were frequently disputable. When, through his agency, notification of epidemic disease became compulsory, it was resented by a considerable portion of the medical profession of the city, but the medical officer of health dealt with the opposition in a tactful and successful manner. He was patient with and most willing to assist medical practitioners, especially the younger men, by placing his services at their disposal and by helping them in doubtful cases.

In his early years he was a keen angler, and for many summers in succession he made his way to the North of Scotland, his companions in sport being Dr. Wilson, formerly of Newcastle, and the late Thomas M. Dodd and Dr. Calcott. Dr. Armstrong wrote several songs in praise of angling, some of them of considerable merit.

On October 8th his body was laid to rest in Benwell churchyard beside that of his wife, who predeceased him by many years. The funeral was attended by the Lord Mayor of Newcastle-on-Tyne, by several of the city councillors and officers of the health department, also by the president, professors, and lecturers of the College of Medicine. Professor Kerr and Dr. Ranken Lyle were unavoidably absent from the memorial service.

Armstrong left two daughters, one married to Dr. Henry Davison of Wylam-on-Tyne, and the other to Mr. Winter Blith, son of one of his old friends.

#### HENRY BRUNTON ANGUS, M.B. M.S. DURHAM, F.R.C.S. (LOND.)

*Emeritus Professor of Surgery, University of Durham College of Medicine, Honorary Consulting Surgeon, Royal Victoria Infirmary, Newcastle-on-Tyne.*

MR. HENRY BRUNTON ANGUS died on October 4th, 1927, at his residence, 5 Edlington Road, Newcastle-on-Tyne. For more than a year he had been in failing health, and for many months the shadow of his approaching end, which from the nature of his illness seemed inevitable, had been on the hearts of his friends. A man of strong physique and commanding presence, his term of life might have been expected to be long, and his death at the early age of 59 years, although long awaited, has come with an element of shock to his colleagues.

Henry Brunton Angus was born on December 7th, 1867. He was the son of James Ackworth Angus, a well-known Newcastle medical man. He was educated at the Newcastle Royal Grammar School, and afterwards became a student at the Durham University College of Medicine in Newcastle, taking the degrees of M.B., B.S. in 1890. Making up his mind early to take up surgery, he worked for the Primary Fellowship, and to this end took out courses of study at St. Bartholomew's Hospital and at Cambridge. In 1891 he obtained the diploma of M.R.C.S., L.R.C.P. (Lond.), in 1900, the degree of M.S. Durham, and in 1902, the diploma of F.R.C.S. (Eng.). A keen anatomist, he was for some time a demonstrator of anatomy at the College of Medicine, Newcastle. Beginning in 1891 as house-surgeon, he was continuously associated with the Royal Victoria Infirmary, Newcastle-on-Tyne, until his resignation in April last on account of ill health. In his earlier years he served as resident medical officer at the Newcastle Dispensary, and as resident house-surgeon at the Southport Infirmary and Dispensary. At the Newcastle Infirmary he was appointed an assistant surgeon in 1895, and became a full surgeon in 1905. On his resignation, in recognition of his services to the hospital he was elected an honorary consulting surgeon. At the Newcastle Infirmary he was a conscientious member of various committees, and devoted his time unsparingly to matters relating to the general management of the institution. He was honorary consulting surgeon to the Thomas Knight Memorial Hospital at Blyth. At the College of Medicine he was appointed lecturer in surgery in 1909, and on the resignation of Professor Rutherford Morrison, in 1921, was elected to the chair of surgery. When his illness caused him to resign the chair he was elected an emeritus professor of surgery. In 1910 he became a member of the Senate of Durham University, and from 1919 onwards was a member of the Council of the College of Medicine. An active member of the local medical societies, to which he was often to be seen, he had held the office of president of the Newcastle Clinical Society and of the Northumberland and Durham Medical Society. He was a loyal member of the Durham Medical Graduates' Association, and had filled the office of secretary and president.

At the Newcastle Meeting of the British Medical Association in 1921 Professor Angus was vice-president of the Section of Surgery.

Throughout the great war he did good work as a surgeon at the 1st Northern General Hospital, in Newcastle, and held the rank of lieutenant-colonel.

As a surgeon he was a striking example of a man who, having determined to specialize in surgery, and although, by constitution and temperament, not readily taking to academic study, by sheer determination and application not only obtained the highest diploma, but made himself a most competent practical surgeon. Faithful and devoted in his hospital duties, the institution which he served so long always had the first claim on his time. The hospital, its staff and students, formed the main interest of his life, and this not only in his work, but also in his recreations. His colleagues on the staff felt his loss keenly, for by all he was implicitly trusted, and to many of them he was a dear and intimate friend. He was a sound general surgeon, thorough and methodical in all his work. The surgery of the bones and joints interested him particularly, and of late years he exercised his skill in this direction as a surgeon to the Newcastle Pensions Hospital. By precept and example he was always striving to improve the treatment of fractures in the accident room and wards of the Infirmary.

In private work he held the confidence of the public and of a large circle of practitioners. The son of a doctor, he had strict views on ethical conduct, and was particular in his dealings with his professional brethren and patients. An expert in medico-legal work, as it relates to injuries under the Workmen's Compensation Act, his help was often sought in the courts, where his reputation for wide surgical knowledge and absolute fairness gave great weight to his testimony.

His surgical writings are characterized by the thoroughness and accuracy that marked all that he wrote. Most of his papers are to be found in the files of the

the local medical journals and in the Durham University College of Medicine Gazette. To the *British Medical Journal* he contributed, in 1912, "A method of treating damaged intestine without resection" and to the *Lancet*, in 1913, "A case of subcortical cerebral tumour—tuberculous—successfully removed."

His unaffected manliness made a strong appeal to successive generations of students. A good sportsman himself, he was a keen supporter and advocate of all manner of athletics. Jealous for the success of college teams he was always ready to encourage and quick to admonish if he thought the standard of achievement was falling. Himself a notable example of the *mens sana in corpore sano*, his persistent sympathy with every form of student activity earned for him a well-deserved popularity with undergraduates.

By the death of Mr Angus the profession in the North has lost a distinguished ornament and Newcastle one of its most loyal sons. Many of us have never known our college and hospital without his staid figure and we all long miss his kindly smile and cheerful greeting. Modest in the expression of his opinions he could be blunt and outspoken when the occasion demanded. Never failing in an old world courtesy, he was respected by all for his almost boyish candour and a downright straightforwardness and honesty. Free and open in his nature he was endowed at the same time with a gift of dignity that kept away familiarity. He had a wide circle of friends both in the profession and out of it. Though a hard worker he could always find time for play. In his youth he was a prominent Rugby footballer, and later employed his leisure in golf fishing and shooting. Indeed until his last illness overtook him he was remarkable for youthfulness or both body and mind.

Just a week before his death he was made the recipient of a presentation from his colleagues on the hospital staff on the occasion of his retirement. At a largely attended meeting of the House Committee of the Royal Victoria Infirmary two days after his death tribute was paid to his work for the hospital and to his character by Mr R C E Mortimer, the vice-chairman, and by Mr Martin chairman of the staff. Both speakers referred in feeling terms to the loss the hospital had sustained and spoke of his unswerving loyalty and transparent honesty.

A striking evidence of the high esteem in which he was held by the public and the profession was seen in the large attendance at a memorial service held on October 7th at

Jermond Parish Church. His remains were followed from his residence to the church by a large number of his colleagues of the college and hospital staffs and a gathering of students. The church was filled with a sympathetic congregation of mourners drawn from all ranks and classes, including doctors, nurses, and laymen. A number of his patients from the Pensions Hospital, in hospital blue, were present. After the service his remains were taken to Darlington for cremation.

It is on a note of affection for a loyal colleague and friend that we would bring this record of a well spent life to a close. The sympathy of all who knew him will go out to his widow and his two daughters.

A P

H B Auer  
(Dr. H. B. Auer, J. R. C. S. E., Newcastle  
Daily Journal)

Sir Thomas Oliver, consulting physician to the Newcastle Infirmary has been good enough to send the following tribute to the memory of Professor Angus.

The passing of this well known and much esteemed surgeon on October 4th, although not unexpected from the many months of indifferent health it was known he was experiencing owing to a progressive form of aneurism has cast a gloom over the medical profession of the city. Of a bright and happy disposition, fond of sport of which golf and fishing were in recent years most followed, Mr Angus manfully fought the malady which was silently undermining his physique and undoing his strength. During his long illness there occurred from time to time those remissions which are characteristic of the malady and which temporarily raised the hopes of his family and friends. In my friendly visits to him I never found him dispirited nor broken. His courage was an example and a discipline, and will remain a memory. He was one of my old pupils so I followed with considerable pleasure and pride his progress from the time he held his first professional appointment as resident medical officer to the Newcastle Dispensary. I often thought that the occupancy of this post was of great assistance to Angus in subsequent years when he had given himself solely to the practice of surgery. Angus was a popular teacher and a sound and reliable chairman. A good operator, his services were much in request and were appreciated alike by his professional brethren and by the friends and relatives of the one to whom he had had occasion to minister. He was perfectly straight in all his dealings with his fellow men he won and retained the respect of all with whom duty or a friendly gathering brought him into contact. To the widow and her two daughters the sincerest sympathy is extended.

#### WILLIAM SMITH PORTER M.D.

Consulting Physician, Sheffield Royal Infirmary and  
Sheffield Royal Hospital

We regret to record the death of Dr W S Porter at Sheffield on October 5th. His father was a practitioner in Sheffield, where he was born in 1855. After studying medicine at the Leeds Medical School King's College Hospital and Durham University he obtained the diploma M.R.C.S. Eng. in 1878 and the L.R.C.P. Lond. in 1879 graduated M.B. Durolm in the same year and proceeded M.D. as gold medalist in 1881. During his student days in London he acted as dispenser to Lord Lister.

Dr Porter commenced practice in Sheffield and was appointed to the staff of the Sheffield Dispensary now the Royal Hospital. In 1887 he became physician to the Sheffield Royal Infirmary, from which post he retired in 1920. He lectured in medicine and physiology in the Sheffield University College prior to the foundation of the University. He took an active part in the Sheffield Medical-Chirurgical Society, and when honorary secretary in 1890 he travelled with the late Dr Dinnern Burgess to Berlin to investigate and report on Koch's work on tuber-

closis. He was subsequently elected president of the society. In 1890 he was one of the first to draw attention to the prevalence of lead poisoning in Sheffield, this was subsequently traced to the water supply. During the war he served on the staff of the 3rd Northern General Hospital, with the rank of lieutenant-colonel.

When the British Medical Association met in Sheffield in 1908 he was invited to edit the Handbook of the meeting, which work he undertook with great enthusiasm and did extremely well. He wrote the general introduction dealing with the principal events of the city's history and also acted as chairman of the Local Publications Subcommittee. He was an authority on the archaeology of Sheffield and the surrounding district, and published many valuable papers on this subject. In 1926 he was president of the Sheffield Literary and Philosophical Society, and a lecture he delivered was published afterwards under the title of

"Notes from a Peakland parish." This was based on his research into the history of the village of Hope in Derbyshire where he had resided for many years. Dr Porter had been president of two other local societies, the Sheffield Microscopical Society and the Sheffield Press Club.

In his early days he was a keen Alpine climber, and until recently his favourite recreation was long walks over the Derbyshire hills and moors.

A COLLEAGUE writes: By the sudden death of Dr W S Porter the medical profession of Sheffield has lost one of its oldest and most respected members, his loss will be felt most keenly. By common consent he stood for and personified the highest ideals of our profession. A man of wide general culture, the soul of honour, a model of courtesy, and kindly consideration for patients and colleagues alike, he possessed in an eminent degree all those qualities of mind and heart which go to make an English gentleman. Those who can look back to the days when he was their chief, and later their colleague, at the Royal Infirmary, think of him with very great affection, and during the later years of his life, after his retirement from the active work of the hospital, his help and advice were often sought by his professional brethren, when difficulties had to be straightened out, or decisions made, with the certain knowledge that the help and advice he gave would be based upon wide experience, sound judgement, and, above all, a disinterested love of truth and right. We revere his memory, and his death recalls to the mind of the writer an epitaph on the tomb of a doctor of old time, whose high character was commemorated on the walls of the cathedral near which he lived, as one "qui Rem Medicum in hoc clauso et civitate adjacenti per quinquaginta annos probe et feliciter exercebat."

Dr NEWCOMB WHITELAW BOURNS died on October 2nd at Wincanton, after an illness of nine months. He was born at Crick-on-Shannon in 1852, and received his medical education at St Bartholomew's Hospital. He took the diploma of M.R.C.S. in 1879, that of L.R.C.P. Ed in 1880, and the degree of M.D. Brux. in the same year. At St Bartholomew's Hospital Bourns learnt from the senior anaesthetist, Mills, the administration in sequence of nitrous oxide, ether, and chloroform, which he adopted in hospital and private work with great success and with remarkable safety to patients. After settling in South Kensington he was appointed anaesthetist to the Cancer Hospital, and in 1887 became the first regular anaesthetist to Westminster Hospital. With these duties he combined private practice, and his competence and pleasing manner were highly appreciated by his many patients. On retiring he joined some long-standing friends in Somersetshire, where in the Blackmoor Vale he had scope for his hobbies, particularly gardening and shooting. An unfortunate motor accident laid him by for a year, but he recovered to enjoy life again.

## Universities and Colleges.

### UNIVERSITY OF LONDON MATRICULATION EXAMINATION

At the September matriculation examination of the University of London 48 passed in the first division and 413 in the second division, in addition 25 took the supplementary certificate in Latin.

### UNIVERSITY COLLEGE

A public lecture, with cinematograph illustrations on the static reflexes of Vagus—How animals get right way up and keep so—will be delivered by Professor Arthur J. Hall, M.D., on Tuesday next October 18th, at 5 p.m. The chair will be taken by Dr F. M. R. Walsh. The lecture will be given in the Physiology Theatre (entrance Gower Street). It is open to the public without fee or ticket.

### KING'S COLLEGE

Dr Duncan MacCallum Blair, lately lecturer on regional anatomy in the University of Glasgow, has been appointed Professor of Anatomy at King's College London in succession to Professor J. Barclay Smith, retired. Professor MacCallum Blair gave an inaugural lecture at King's College last week entitled "The brothers Hunter—A hindmark in anatomy." His main thesis was that the abiding lessons of Hunterian anatomy were twofold: first, there was a living anatomy—form was studied in an effort to elucidate function; secondly, John and William Hunter gained their knowledge of form and function by repeated direct observation and careful experiment in both human and comparative anatomy. They established anatomy as an

experimental science. When the Hunterian principles had dropped out of sight, then anatomy had suffered if it was to remain a living progressive science it must be pursued in the spirit of the brothers Hunter.

## Medical News.

DR DOROTHY C. LOGAN ("Miss Mona McLennan") succeeded in swimming across the Channel from Cap Gris-Nez to Folkestone during the night of October 10th, her time 13 hours 10 minutes, which establishes a "record" for women Channel swimmers. The shortest time in the case of men swimmers is 11 hours 5 minutes, which was taken by G. Michel in September, 1926. Dr Logan graduated M.B. B.S. Lond. in 1912, and proceeded M.D. in 1915. She has appointments at King's College Hospital, the London Dispensary Hospital, and the Mothers' Hospital at Charing Cross, and is a member of the British Medical Association.

THE annual meeting of Fellows and Members of the Royal College of Surgeons will be held at Lincoln's Inn Hall on Thursday, November 17th, at 3 p.m.

THE Chadwick Trustees announce that the second annual Malcolm Morris memorial lecture will be given by Dr W. G. Savage in the Hastings Hall of the British Medical Association's House, Tavistock Square, on October 17th at 5.15 p.m. Dr Savage has chosen food poisoning for his subject. On October 27th Mr W. Hiles, curator of the Chelsea Physic Garden, will give a Chadwick lecture on tropical vegetation and some of its uses to man. Major H. Baines will lecture twice in November on the history of housing, and early in December Professor Lelean will give a dissertation on the mind and health.

THE thirty-ninth Congress and Health Exhibition of the Royal Sanitary Institute will be held at Plymouth from July 16th to 21st, 1928, under the presidency of Viscount Astor. At the meeting of the Royal Sanitary Institute on Friday, October 28th, in the council chamber, Town Hall, Newcastle-on-Tyne, discussions will take place on the influence of overcrowding upon tuberculosis, with special reference to the new housing schemes, on the new Factories Bill, and on the smoke problem on Tyneside. The chair will be taken at 4.30 p.m. by Dr Charles Porter.
